

**INFLUENCE OF PERSONALITY AND ALCOHOL-USE ON
RISKY DRIVING BEHAVIOUR AND ACCIDENT PRONENESS
AMONG INJURED DRIVERS TREATED IN A TEACHING
HOSPITAL IN OSHOGBO, NIGERIA**

BY

AKINNIYI, ROTIMI JACOB
B.Sc (UNN),M.Sc(OAU)
MATRIC NO: 142077

**A DISSERTATION IN THE DEPARTMENT OF PSYCHOLOGY
SUBMITTED TO THE FACULTY OF THE SOCIAL SCIENCES
IN PARTIAL FULFILLMENT OF THE REQUIREMENTS FOR
THE DEGREE OF MASTER OF PHILOSOPHY OF THE
UNIVERSITY OF IBADAN**

**SUPERVISOR
PROF. (MRS.) OSINOWO H. O.**

FEBRUARY, 2015.

CERTIFICATION

I certify that this work was carried out by **AKINNIYI, ROTIMI JACOB** with **MATRIC NO: 142077** in the Department of Psychology, University of Ibadan, Ibadan, under my supervision.

Supervisor

Professor Helen O. Osinowo
B.A. (Soc. Sci.) London
M.Sc. (Soc) Ibadan
M.Sc. (Clin. Psych) Ibadan
Ph.D. (Ibadan)

Date

UNIVERSITY OF IBADAN LIBRARY

DEDICATION

THIS DISSERTATION IS DEDICATED TO GOD ALMIGHTY FOR HIS
KINDNESS AND MERCIES.

UNIVERSITY OF IBADAN LIBRARY

ACKNOWLEDGEMENTS

It is a great pleasure to express my profound gratitude to my supervisor, Professor Helen O. Osinowo for her scientific guidance and supportive attitude throughout this work. You provided your valuable time and expertise to make sure that this work was successful. May the Lord in His infinite mercy continue to guide and protect you.

I am very grateful to the Head of Department Prof. B. O Ehigie for his assistance and encouragement throughout this work. I am much grateful to all the lecturers in the Department. Specifically, I will like to appreciate Prof. Balogun, Prof. Sunmola, Prof. Udegbe, Dr. B.O. Olley Dr. Alarape, Dr Ekore, Dr. Okurame Dr. (Mrs) Chowven, Dr. Olapegba, Dr. A.O. Adejumo, Dr. Okhakume, Dr. Asagba and Dr (Mrs.) Adejuwon for their most invaluable advice throughout my study.

This is to express my profound gratitude to the postgraduate colleagues in the Department, particularly Mr. Oyeleke (aka Baba), Dr Gbemi Olukolade and Mr. Ishola (aka Pavlov) for their educational advice and support. The Lord will continue to guide you in all your endeavours.

The contributions of Mrs Ajakaye and Mrs Adekola are on record. Their motherly roles towards my success cannot be forgotten and may God Almighty raise helpers for you at the point of their needs. All members of non-academic staff are very wonderful and helpful. I say; 'thank you' to all. I wish to express my sincere appreciation to Prof. Adejuyigbe Sanya (former CMD OAUTHC) and to all my professional colleagues. My loving sister Mrs. Mary Ajala; my prayer partner, Mrs Alesinloye Bolanle; Mr Akinbode Sunday Johnson and all my pastors, I appreciate you all!

Finally to my enviable, cool-headed and understanding wife, Mrs. Akinniyi, Dorcas Aanu for her prayers, understanding and support throughout this work. My sincere appreciations go to all my children for their understanding, endurance and cooperation. I cannot fail to mention those who initiated my interest in education. They numerous indeed. First and foremost, my loving parents Late J.A. Akinniyi & R. A. Akinniyi, Prof. Sola Olowu, Prof. Chris Ajila and Dr. E.E. Idehen. I owe my thanks to them for their efforts in making me what I am today and for providing me the avenue to experience and acquire knowledge in life. I heartily thank you all.

ABSTRACT

Road traffic accidents in Nigeria have been on the increase in recent years despite the various programme designed to reduce the carnage on Nigerian roads. Various factors have been implicated in accident aetiology and these include personal predilection to risky driving behaviour, accident proneness and alcohol use. Personality traits of extraversion and neuroticism have been implicated in accident proneness based on several studies carried out in developing countries. Therefore, this study examined the influence of personality types and alcohol use on risky driving behaviour and accident proneness among injured drivers treated in Ladoke Akintola University of Technology Teaching Hospital (LAUTECH), Osogbo, Osun State.

A cross-sectional survey research design was used for the study. One hundred and twenty participants were selected from LAUTECH Orthopaedic, Accident and Emergency Physiotherapy Unit and outpatients' clinic using consecutive recruitment. A questionnaire consisting of five (5) sections made up of standardized instruments was used in collecting data for the study. Informed consent and permission were obtained from both the participants and the hospital administrations before administering questionnaire on the respondents. Five (5) hypotheses were tested using t-tests and multiple regression analysis at $P < 0.05$ significant level.

Results indicated that female participants were more prone to accident than their male counterparts { $t(118) = 4.03; P < .01$ }. Also, those who had higher education scored higher on accident proneness than their counterparts with low education. { $t(118) = -2.05, P < .05$ }. Male drivers exhibited higher risky driving behaviours than female drivers { $t(118) = 5.518; P < .01$ }. Those who are lower in educational qualification are more risky in driving than those with higher education { $t(118) = 2.617; P < .05$ }. Personality types (openness, conscientiousness, extraversion, agreeableness and neuroticism) and alcohol use predicted risky driving behaviour with joint contribution of 29.0% to the variance. Neuroticism ($\beta = -0.29$), openness to experience ($\beta = 0.2$) and alcohol use ($\beta = 0.40$) independently predicted risky driving behaviour. Personality types of extraversion ($\beta = 0.59$) and agreeableness ($\beta = 0.59$) independently predicted accident proneness among the injured drivers.

Alcohol and personality types influence accident proneness among injured drivers surveyed. This suggests that an abridged psychological assessment to identify the risk taking drivers before issuance of driver's license and periodic re-evaluation with psycho-education be adopted.

Keywords - Personality traits, Alcohol use, Risky driving behaviour, Neuroticism, Openness to experience traits, Accident proneness.

CHAPTER ONE

INTRODUCTION

1.1 BACKGROUND TO THE STUDY

Risky driving behaviour constitutes any risky driving undertaken by the driver which increases the likelihood of the driver being involved in a car crash and may harm or fatally injure the driver themselves, their passenger(s), and other road users such as pedestrians, cyclists, drivers and passengers in other vehicles. The factors that contribute to crashes include inadequate lighting and slippery surfaces due to vehicle defects such as brake failure and worn out tyres (Sobey and Taylor, 1980, cited in Norris, Matthews and Riad, 2000)

Risky driving behaviours reflecting non-compliance with general road rules included using a handheld mobile phone whilst driving, not wearing seatbelts, driving after consuming illicit drugs and carrying more passengers than the car was designed for. Definition includes risky driving behaviour which the driver may perform with or without being aware of the increased risks, such as travelling at the posted speed limit during heavy rain. In other words, it encompasses both intentional and unintentional behaviours that increase crash. Of particular concern to the researcher is both the intentional or unintentional risky driving behaviour, such as driving in excess of posted speed limits or after drinking alcohol. A comprehensive understanding of the risky driving behaviour of drivers is fundamental if effective countermeasures are to be developed and implemented.

Many drivers choose to drive and behave in ways that increase their risk of crashing; for example, Elvik, Christensen, and Amundsen (2004) concluded that a relationship exists between mean traffic speed number and severity of crashes that occur on

a road. Non safety belt -use has been associated with increased risk of injury and death in a crash. Driving a vehicle is a psychomotor task and continually monitoring the roadway and anticipating the actions of other drivers are critical for safely operating a motor vehicle and reducing accident proneness. A distracted or inattentive driver is likely to have delayed recognition or no recognition of information necessary for safe driving and is accident prone (Saats et al. 2003). Driver distraction and inattention have been cited frequently as contributing factors in crashes (Hendricks, Fell and Freedman, 1999; Klauer, Dingus, Neale, Sudweeks and Ramsey 2006).

Risky driving behaviour has been identified as an important contributor to road crashes, although its role is not comprehensively understood. These include speeding, drink-driving, driving while fatigued, and not wearing seat belts. Research on drivers' risky behaviours and risk perceptions is crucial to understanding why accident rates are on the increase. There is much to be learnt about the impact of drivers' risky driving and how it is associated with their increased risk of crash. Recent research confirms that certain risky driving behaviours are more prevalent among drivers. These include high-level speeding and speeding for the thrill of it, following too closely to the vehicle ahead, violating traffic rules, not using seatbelts, using mobile phones while driving, text messaging, driving during high-risk night-time hours, and driving older vehicles. In addition, certain driving behaviors have been demonstrated to be of a higher risk for driving. These include carrying peer groups or multiple passengers and driving under the influence of alcohol, even at low concentrations.

Road traffic accidents occur worldwide but the incidence is more in developing countries due to human error arising from the way of life, personal characteristics, mechanical and road design (Balogun,2006). However, the human nature is at the centre of the causes of accident rates in Nigeria. These necessitate the need to identify those characteristics traits and related factors precipitating problems of increasing accident rates towards a more emphatic intervention in reducing the carnage on Nigerian roads.

Accident is an unplanned, unexpected and undesirable occurrence that disrupts the flow of normal interactions and relationship, which may result in inconveniences, injuries, property damage or death (Yisa, Agbonkhese, Akanbi, Aka and Mondigha, 2013). Accidents on the road are caused by interaction of human, vehicular and environmental factors which the driver found incomprehensible at the movement (Balogun, 2006). Annually, about 1.24 million people die each year as a result of road traffic crashes without action, road traffic crashes are predicted to result in the deaths of 1.9 million people by 2020 (Yisa, et al, 2013).

From 1960 through 2004, Nigeria experienced 995,112 cases of road accident, in which 283,240 lives were lost and 833,770 were injured. The FRSC (2004) mounted drastic efforts to reduce the carnage, by 2004 the number of road accidents was 14, 279 and recent statistics recorded between 2006 and 2008 show that more still need to be done. In January 2010, statistics made available by the Federal Road Safety Corps indicated an upsurge in road accident victims in the country with comparative analysis of the 2009 and 2008 exercise showing a 13 percent increase. Out of this figure, Zone RSII command, comprising of Osun, Ondo and Oyo states posted the highest number of 2,908 offenders, 3,141 traffic offences with 769 and 791 vehicles and motorcycle impounded

respectively. Road traffic accident can be caused by a single factor or a combination of factors. However, the constellations of causes have been summarized to three basic roots these include human, vehicular and environmental factors. The latter two are also believed to have resulted in errors from a human effort. As such, most safety studies come to the conclusion that vehicle operator or driver factors (or human error) are the main causes of accidents. Nevertheless, such a conclusion has not proved to be efficient in its capacity to offer adequate means to fight against this menace. In an effort to better qualifying accident causation, this study looks at factors precipitating accident proneness and risky driving behavior leading to road accidents.

Prediction of accident occurrence and assessment of risky driving behaviour is based on the premise that accidents in general are not due to chance alone (Visser, Pijl, Stolk, Neeleman and Rosmalen, 2007), focuses specifically on analyzing circumstances and factors that affect the risky driving behavior as one of the causes of accidents while he believes that human factor is one of these. One perspective on how circumstances present a risk of accident to humans emphasizes how the human system in general is prone to making errors in a particular circumstance. Recent research has shown, for instance, that car crashes could be predicted from risk-taking personality trait and accident proneness (Iverson and Rundmo, 2002).

Road accident is also believed to occur as a result of accident proneness and risky driving behaviour among road users. The human component in accident involvement is difficult to study because of the lack of consensus on what defines accident proneness. Accident proneness is a concept that refers to an enduring or stable personality characteristics that predisposes an individual towards having accidents (Haddon, Suchman

and Klein, 1964). Accident proneness is a deceptively easy term; it has been described as “an error with sad consequences but the relationship between the preceding behaviour and the consequences is not at all simple.

Accident proneness is the tendency of an individual to experience more accidents than otherwise identical individuals (in terms of basic personal characteristics like age, gender and place of residence) due to stable personality characteristics. We did not include exposure to risk as part of the definition itself because the extent to which individuals expose themselves to risk may be largely determined by personality characteristics (Mahmoudi, Mohammadfam and Bagi, 2013).

The successful reduction of the incidence of human factors in road accidents and crashes requires a good understanding of contributing factors. However, literature trend and empirical studies have not directly examined these variables beyond its impact on accident rates and less in terms of precipitating factors. Fernandes and Hatfield, (2006) have identified that different factors predict these variables. They located the advent of accident proneness and risky driving behaviours in the development pattern engrained in human innate characteristics interacting with the environment.

The driving behaviours are influenced by many factors including knowledge, awareness, skills, experiences, characteristic and the conditions found in the motor vehicle and the various conditions of the community in which drivers live. Individual characteristics that have been found to be related to motor vehicle morbidity and mortality among drivers include race, age, gender, cognition, driving experience and level of education.

This study also identified that vehicular accident is often resident in error of human judgment and deliberate omission or addition of certain acts while driving resulting from the drivers to react or act in certain ways due to their innate characteristics or intentions. The act is described as engaging in behaviours or conditions having the possibility of incurring an incidents or events.

Alcohol or alcoholic substances fall among the classes of drugs which exert their major effects on the brain and physiological functioning, resulting in such effects as sedation, stimulation or change in mood or behaviour (Burns, 1988) and are potentially habit forming. Today, alcohol and alcohol distillates (For example *Ogogoro*: illicit gin) remain the elixir of life that readily available in motor parks and roads side kiosk. Alcohol remains the most widely abused substance by drivers with the reasons that it increases alertness, strength for physical work and reduces the impact of stress on drivers (UNDCP, 2006). Several studies have identified the increasing role of alcohol intake in road crashes in Nigeria (Nzegwu et al, 2011).

Available alcoholic beverages in Nigeria include beer and wines, fortified wines and local alcoholic cocktails popular in the motor parks in southwest Nigeria such as “*jedijedi*” (Pile mixture), “*Opa-eyin*” (Back pain elixir) (Nzegwu et al, 2011). All these are not only freely available but are sold without any restriction in public bus stations in Nigeria. After ingestion, its absorption is rather fast in the body and its high alcohol concentration in the blood leads to poor ability to see or locate moving lights correctly, ability to judge distances and increased tendency for risk- taking (Nzegwu et al, 2011).

Alcohol is consumed by large proportions of adults in most countries around the world. Though not causing significant problems for most drinkers, alcohol use is associated with numerous negative consequences for the drinker and society at large. Globally, alcohol causes 3.2% of all deaths or 1.8 million deaths annually and accounts for 4.0% of disease burden. Many of these deaths are the result of injuries caused by hazardous and harmful drinking. Of the total number of alcohol-attributable deaths, 32.0% are from unintentional injuries, and 13.7% are from intentional injuries. This means that about half of the deaths attributable to alcohol are from injuries.

The problem of alcohol-related injuries is particularly alarming in many low and middle -income countries, where alcohol consumption is increasing, injury rates are extremely high, and appropriate public health policies have not yet been implemented. While there is little doubt that alcohol consumption is associated with injury occurrence, less is known about the level of risk at which various drinking patterns, quantities of alcohol consumed, or drinking situations place the individual at risk for accidental injury.

The path to accident proneness shows that high concentration of alcohol in the blood stream is that its victims' reactions are slower, concentration span is shorter and at 100-120mg/dl level of concentration euphoria sets in and with it, an over-estimation of one's abilities leading to reckless driving. International studies show that alcohol is estimated to be a factor in 20-30% of all accidents (Nzegwu et al, 2011). There is no prior documentation of alcohol being related to accident proneness. Based on this premise, this study examines the contribution of alcohol use to accident proneness and risk driving behavior among drivers who have experienced road crashes in Nigeria.

Personality traits are the underlying factors affecting peoples' estimations, attitudes and behavioural tendencies. Personality can be defined as a collection of emotion, thought, and behaviour patterns unique to a person that interacts to determine how individuals perceive and respond to events. In the driving context, personality can influence risky driving behavior and driving outcomes such as traffic offences and crash involvement. Extroversion is associated with being impulsive and this has been found to be a feature in people who have car accident (Furnham and Heaven, 1999). Personality traits have been reduced to five dimensional domains called the "Big Five" personality traits based on extensive years of study (Costa and McCrae, 1996; Golberg, 1990). These five personality traits are used to understand the relationship between personality and various behaviors. These traits include:

- Openness
- Conscientiousness
- Extraversion
- Agreeableness
- Neuroticism

Openness to experience reflects the degree of intellectual curiosity, creativity, and preference for novelty and variety. Conscientiousness is a tendency to show self-discipline, act dutifully, and aim for achievement conscientiousness also refers to planning, organization, and dependability. Extraversion includes energy, positive emotions, assertiveness, sociability, talkativeness, and the tendency to seek stimulation in the company of others. Agreeableness is the tendency to be compassionate and cooperative rather than suspicious and antagonistic toward others. Neuroticism is the

tendency to experience unpleasant emotions easily such as anger, anxiety, depression, or vulnerability. Neuroticism also refers to the degree of emotional stability and impulse control which is sometimes referred to as emotional stability.

All these factors are assumed to represent the basic structure behind all personality traits. These five factors were defined and discovered by several different researchers during multiple periods of research. However, as a result of their broad definitions, the Big Five personality traits' are not nearly as powerful in predicting and explaining actual behavior as are the more numerous lower-level, specific traits. According to Santos (1995), psychological variables (such as personality) are associated with high levels of inter-individual variability, which can have a significant impact on the driving behavior.

Numerous studies have investigated the relation between emotional stability and driving style, driving anger, aggression in traffic and reactive aggression (Booth-Kewley and Vickers, 1994, Herzberg, 2009, Bettencourt, Talley, Benjamin and Valentine, 2006). Jovanovic et.al(2010) highlight that people with high scores on the emotional stability factor show a high level of physical and verbal aggression in traffic.

Extraversion, which means the pleasure of interacting with others, the tendency to be assertive, sociable, energetic, outward (John and Srivastava, 1999) was studied in relation to aggressive driving behavior with some studies finds a positive relation between extraversion and reckless driving (Renner and Ander, 2000). Dahlen and White (2006) showed that extraversion predicts reckless driving and traffic accidents, the high level of extraversion being one of the causes of road accidents.

People with high scores on the openness factor tend to be characterized by aesthetic appreciation, values, idea acceptance, self-actualization, personal growth and development (McCrae and Costa, 2006). Taubman - Ben-Ari and Yehiel (2011) studied the openness factor in the context of driving styles, finding a positive relation between openness and careful driving style while between styles characterized by aggressive, anxious and hostile behavior, there was no significant association with openness. Among the few studies that have found the openness factor associated with aggressive driving behaviour is that of Dahlen and White (2006), the authors showing a negative link between openness and reckless driving, individuals with high scores on openness factor being less prone to engage in risky traffic than those with a low score.

People with high scores on agreeableness factor are inclined to trust others, are altruistic, empathic, and tolerant, are likely to forgive, generous and gentle (John and Srivastava, 1999, McCrae and John, 1990). People with a high score on agreeableness practice careful driving style, and those with a low score drive in anger, reckless, anxious and desolate way (Taubman - Ben - Ari and Yehiel, 2011). It has been shown that there is a negative relation between agreeableness and violation of traffic rules, people with low scores on agreeableness factor, often violating traffic rules. Also, a negative association was found by Jovanovic et.al (2010) between agreeableness manifested anger while driving.

High conscientiousness is characterized by orderliness, self-discipline, organization, intention to do and resolve things and problems (John and Srivastava, 1999). Arthur and Graziano Jr. (1996) have demonstrated the existence of a negative relation between conscientiousness and involvement in accidents. Thus, those with a high

score on this factor, being characterized by organization and self-discipline, are rarely involved in traffic accidents than those with low conscientiousness scores. Jovanovic et.al (2010) show that physical aggression and verbal aggression manifested while driving relate negatively with conscientiousness, those with high scores on this factor manifesting a reduced physical and verbal aggressive behaviour when driving, than those with low scores. Looking at personality traits, risky driving behaviour and accident proneness, individuals are compelled to test new “personal potentialities” closer to the infringement of the law (Sousa, 2000)

Age is associated with accidents in a number of ways. Firstly, it influences the number and severity of the hazards individuals are exposed to. Secondly, it is connected to the competence that individuals have at particular tasks, such as crossing the road, their skills and attitudes. In younger drivers, the judgment of depth and speed may not be fully developed and they may as well be as unaware of some dangers. For the older person, the problem is limited mobility or failing eyesight (Donaldson 2000).

1.2 STATEMENT OF PROBLEM

The magnitude and trend of the crash Worldwide is heart-breaking, unfortunately, the rising tide of this global problem has continued to outstrip effort to curtail it. The chance of vehicle killing a road user in Nigeria was 47 times higher than in Britain according to Atunbi (2012). Road traffic crashes are one of the world’s largest health and injury prevention problems. The problem is more acute because the victims were overwhelming healthy prior to their crashes. According to the World Health Organization, (2010) more than a million people are killed on the worlds’ road each year. A joint report

between WHO and World Bank (2006) noted that in spite of the growing burden of road traffic injuries, road safety has received insufficient attention at local and international level due to lack of awareness on the socio economic scale of the problem and that road traffic crashes and injuries do not belong to any specific agency in most Countries.

The use of psychoactive drugs followed by driving has been an issue of continual concern to law enforcement officers, physicians, attorneys, forensic toxicologists and traffic safety professionals in the U.S. and throughout the world (National Highway Traffic Administration, 2005). Alcohol consumption has been identified as the most important factor in road traffic accidents (European Transport Safety Council, 1995). The relationship between the blood-alcohol level and risk of accidents has been known for a long time. It was estimated that driving under 35% level of alcohol for those with light injuries and 10% for those without injury (Council on Scientific Affairs, 1986).

The role played by alcohol use on road safety has become subject of increasing interest, these substances can reduce driving performance and increase accidents risk; compared to other areas of traffic accident research, the study of social psychological and behavioral correlate of crashes involvement has attracted only a relatively small number of researchers. Kraus et al (2009) cited several studies which had found that drivers involved in or responsible for traffic accidents differed from their matched control groups in certain psychological trait such as aggression, intolerance of authority, non-conformity and so on. The role of personality trait in traffic accidents has been central in explanations emphasizing accident proneness (Farmer and Chamber 1939, Tillman and Hobbs 1949). The notion that one general personality traits is the cause of drivers ' accident

involvement has ,however been rejected. Still, the influence of personality on driving behavior and accident involvement is not totally abandoned.

One of the personality characteristics that have attracted some attention is the type A behavior pattern, it might be that the urgency to the type A pattern leads people into risky situation. Among the myriad of factors is the contribution of the moderating role of alcohol use and enabling personality's trait of the drivers in Nigeria. Nigeria drivers are believed to be accident prone due to their life styles and the nature of their jobs (Obot, 2002, Odejide and Morakinyo 2007). Some salient facts emerging from these various studies on substance abuse in Africa (For example Obot 2002, Gureje, 2007), affirmed that Nigeria drivers are at risk population for alcoholic substance use.

The brief review of literature above suggests that a number of factors may explain the causes, consequences of alcohol use "accident proneness". Therefore, the following specific questions were however noted in relation with the study. What is the relative variance in personality factors accounted by risky driving behaviour and accident proneness? Finally, what is the influence of religion, belief, mood, intolerance, aggression, age and experience in the relationships between risky driving behaviour and accident proneness?

Based on these premises, the following questions arise:

Research Questions

- (a) Will age influence accident proneness and risky driving behaviour?
- (b) Will level of education influence risky driving behaviour?
- (c) Will level of education influence accident proneness?

- (d) Will personality factors play a significant role in predicting accident proneness and risky driving behaviour?
- (e) Will alcohol use play a significant role in predicting accident proneness and risky driving behaviour?
- (f) Will the combination of personality and alcohol use play a significant role in predicting accident proneness and risky driving behaviour?

1.3 PURPOSE OF STUDY

The study main aim was to examine personality traits and alcohol use as predictors of driving behaviour and accident proneness among injured drivers. In the light of this study, the specific objectives were to –

- 1 investigates the influence of socio-demographic factors on accident proneness and risky-driving behaviour;
- 2 assess the influence of personality traits on accident proneness and risky driving behaviour;
- 3 determine the influence of alcohol use on accident proneness and risky driving behavior.
4. assess the joint influence of personality traits and alcohol use on accident proneness and risky driving behaviour..

1.4 RELEVANCE OF THE STUDY

A research into accident proneness and risky driving behaviour with information on the incidence, severity and effects of personality, alcohol use against driving behaviour and accident proneness adds to existing scientific literature with respect to the influence of these variables on accident proneness and risky driving behaviour. This study developed a new instrument to measure risky driving behaviour. This contributes to psychometric methodology as it provides a tool for screening and assessing drivers for risky driving behavior. Drivers found to score high on could be counseled about safe driving behaviour deconditioning them so that they can adopt a safer and better driving behaviour.

This study contributes to the present practice of clinical health psychology as provides the need to include psychologists especially the clinical health psychologist to work as members of multidisciplinary teams in the public health sectors to provide psycho-education and cognitive behaviour therapy for those who engage in risky driving behavior. The study will add to knowledge on understanding what risk factors contribute to the occurrence of road traffic accidents and related injuries in Osun state. The data obtained in this study, can be used by the road safety authorities for planning and evaluating road safety measures. The data can also be utilized by the health authorities and possibly at the nation level for planning health care delivery. The recommendations given if considered are going to benefit the public at large on prevention of road accidents. The data can also be utilized as baseline data in future related research.

Furthermore, evidence has not clearly distinguished the role behaviour as distinct factors in predicting accident; hence, this study will extract the common specific driving behaviour as applicable to Nigeria drivers, even though various studies have been

conducted in other parts of the world, this study is considered as exploratory in Osun State because it is paying particular attention to the drivers or motorists in the area.

The findings of this study will be helpful to all drivers in preventing frequent accident/death on our roads. The result will be useful to corps marshal for effective follow up and strategies to improve the drivers' driving behaviour.

UNIVERSITY OF IBADAN LIBRARY

CHAPTER TWO

THEORETICAL FRAMEWORK AND REVIEW OF LITERATURE

2.1 THEORETICAL BACKGROUND

The scope of this chapter is to present an overview of basic propositions that can help in fostering an understanding of the role of personality and alcohol use in risky driving behaviour and accident proneness. Theories have been selected for review include the following: Risk Homeostasis theory, Disposition theory of personality and Big Five model. In this chapter, the trend of accident rate and overview of Nigeria's transport policy were looked into while classification of some key concepts were dealt with.

2.2 THEORIES

2.2.1 Risk Homeostasis Theory

Risk homeostasis theory maintains that in any activity, people accept a certain level of subjectively estimated risk to their health, safety and other things they value in exchange for the benefits they hope to receive from that activity (transportation, eating, recreation, drug use and so on). In an ongoing activity, people continuously check the amount of risk they are exposed to. They compare this with the amount of risk they are willing to accept and try to reduce the difference to between two to zero. Thus, if the level of subjective experienced risk is lower than is acceptable, people tend to engage in actions that increase their exposure to risk. However, the level of subjective experienced risk is higher than is acceptable; they make an attempt to exercise greater caution. Consequently, they will choose their next action so that it is subjectively expected amount of risk matches the level of accepted risk. During the next action, perceived and

accepted risks are again compared and the subsequent action is chosen in order to minimize the difference and so on.

Each particular adjustment action carries an objective probability of risk of accident thus; the sum of total adjustment actions across all members of the population over an extended period of time (one or several years) determines the temporal rate of accidents in the population. These rates, as well as more direct and frequent personal experiences of danger, in turn influence the amount of risk people expect to be associated with various activities, and with particular actions in these activities, over the next period of time. They will decide on their future actions accordingly and these actions will produce the subsequent rate of human made mishaps. Thus, a 'closed loop' is formed between past and present, and between the present and the future. And in the long run, the human-made mishap rate essentially depends on the amount of risk people are willing to accept.

The theory of risk homeostasis predicts that people become accustomed to some acceptable level of risk, and that when they are required to reduce a risk they are exposed to, they will increase other risks until they have re-established the level of risk they have accustomed to, If drivers are required to wear a seat belt, the evidence suggests that they drive faster and pass other cars more dangerously, putting on make-up and so on, so as to maintain the level of risk they are comfortable with.

According to risk homeostasis theory, an individual attempt to optimize the exposure to risk in an activity, where 'optimal' means the degree of risk at which the aggregate needs of that individual are likely to become best fulfilled, instead of aiming at the elimination of risk (Wilde, 2000). People choose an amount and manner of mobility such that the associated level of subjective risk corresponds with the point at which the

expected net benefit is maximal. Interacting with the characteristics of the rule, the characteristics of the individual have a significant effect on rule-governed behaviour. As such taking alcohol and engaging in risky driving are usually towards achieving maximal benefit for being on the road i.e. arriving on time, drive faster than other and making other accept you and your car as king of the road .Certain elements of personality make risky behaviours more likely, simply because they are committed in order to satisfy the individual's personal needs come into conflict with the rule-system.

High scores on certain personality traits such as conscientiousness may be thought of as 'exposing' the individual to the likelihood of committing acts of rule violation. Low conscientiousness traits will seek arousal and this may lead to inappropriate behaviour. A sense of personal control over the particular sensation-seeking behaviour can increase the likelihood that the behaviour will take place, and a highly impulsive individual may engage in the behaviour without waiting to think about the potential consequences. Other elements of personality prescribe the nature of the effects on individual's socialization on these 'risky' behaviours. Breaking rules invites social disapproval, and human socialization processes have ensured that this social disapproval creates an aversive state of arousal in the individual.

The process of internalizing the rule-system leads to large individual differences in the degree to which people are socialized. Differences in socialization will determine whether the risky, rule-breaking behaviour is encouraged or suppressed. Indeed, it determines whether or not any consideration of the social environment takes place at all, prior to the act being committed. This is where the role of education being felt, highly educated persons may or may not view over speeding or eating while driving as risk

behavior in as much the socio-cultural milieu does not frowns at it. Personality traits may be thought of as ‘moderating’ the inhibitory or facilitators effects of social influence. Clearly, a balance is required in terms of perceived control. Individual differences in the tendency to look into the future for potential consequences of behaviour will also determine whether or not a person breaks the rules. They are thus more likely to behave in an inappropriate way than someone who thinks carefully about all the potential future consequences of their behavior which may be a product of educational attainment.

2.2.1a Application of Risk Homeostasis theory to the study: The theory of risk homeostasis predicts that people will consume roughly all the enhanced safety imposed upon them in order to desirable risky activities (for example, more exciting driving to fight boredom, eating or talking on the phone while driving and so on) unless reward or punishment moderates their risk taking behaviour. This model extends that risk taking behaviour is predicated that factors like personality and drug induce high risk taking behaviour. This study opined that personality traits such as high extraversion, openness to experience, and neuroticism coupled with low conscientiousness and agreeableness increases the homeostasis level thereby making the individual desire for speed, negligence and reckless driving to be on the increase leading to accident proneness while reducing the desire for safety and avoidance of road crashes. As such drivers high on extraversion, openness to experience, and neuroticism personality traits coupled with low conscientiousness and agreeableness traits are expected to have higher risky driving behaviour and accident proneness compared to those low on high extraversion, Openness to experience and neuroticism coupled with high conscientiousness and agreeableness. In addition alcohol use is expected to further compound the problem as it

alters the drivers sense of judgment shifting the homeostasis level for risky driving and accident proneness higher due to altered state of the mind.

Driving is an activity that requires maximum concentration that allows the individuals to cope with distraction is their homeostasis risk levels. It have been noted that alcohol use alter the knowledge of timing, slows down the cognitive processing period and affects the muscle tone. As such drivers high on alcohol use while driving are more prone to drive in a risky way and would be more prone to accidents compared to those who did not take alcohol. Thus, the combination of the possession of personality traits that makes drivers prone to risky driving and accidents with alcohol use are more likely to play a major role or be responsible for the increasing incidence of road crashes on Nigeria roads even in the face of increasing legislation against risky driving and alcohol use. Several studies conducted have demonstrated that most drivers (commercial and private) drink alcohol before driving. Alcohol could make drivers feel high behind the wheels. They drive carelessly despite the laws and regulation.

2.2.2 Disposition Theory of Personality

The disposition approach view personality is a combination of stable internal characteristics that defines who people are and what motivates them to behave in certain ways (Murray, 1961 Allport, 1961). These approaches to personality focus on what is termed as personality type and personality trait even the personality combination. Based on personality type, it was said that this attempt goes back to as far as Hippocrates, a Physician of Ancient Greece. He suggested that certain temperaments or basic behaviours' are associated with each of four bodily fluids or humors: phlegm, black bile and yellow

bile. Hippocrates said personality type depends on how much of each humor a person has. The terms for those personality types are: sanguine {angry, irritable}. This notion has great appeal; people tend to maintain some mental schema telling them that certain types of people have a certain “look”. Further, as personality type is seen as a discreet category, traits, and contrast is continuous quality that individual possess in different amount. A person can possess a lot or little of some trait or fall anywhere in between on a measure of that trait. Thus, according to the trait approach each personality can be described in terms of how strong the individual is on various traits such as hostility, sociability and the likes. The notion of traits is very familiar for instance if an individual is asked to describe him or herself would probably do so in terms of traits. Traits are reasonably stable elements of personality that are inferred from behaviour. For instance if one describes a friend as shy, it may be because one has observed social anxiety or withdrawal in that person’s encounter with others. Traits are assumed to account for consistent behaviors in divers’ situation. As such, one would probably expect shy friend to be quiet in most social confrontations. The concept of traits is also found in other approaches to personality for example, Freud linked development of certain traits to children experiences in each of psychosexual development.

Allport {1961} spent thirty years studying traits coming to the normal personality. He also found that many of the labels for these traits refer to the same thing. According to him a set of labels represent a person’s central traits, those that are usually apparent to others and constitute characteristics that organize and control behaviour in many different situation. Centre traits are roughly equivalent to the descriptive term used in letters [for example, Reliable distractible] that are meant to convey what can be

expected of a person most of the time (Phares, 1991), Allport also found what he termed secondary traits as those that are more specific to certain situations and control far less behaviour. In his research Allport often took a homothetic approach that is he carefully compare many individuals terms of the personality traits commonly found in most people to some degree.

Further on the traits perspective, British Psychologists. Hans J. Eysenck (Eysenck and Eysenck, 1977) has focused much of his research on the relationship between two important traits; introversion and extraversion. He has catalogued various personality traits according to where they are situated along these dimensions, and based on the factor analytic method carried out by Eysenck (1985), he eventually obtained three (3) dimensions of extraversion, neuroticism and psychoticism, each of which is measured in continuum or on a dimension.

2.2.2a Application Dispositional Theory of Personality to the study: Central to the Dispositional traits theory is that a person is likely to behave across the situations as well as over time. As such a personality trait is linked to risky driving and accident proneness among drivers. Human behavior and personality traits have been placed on a continuum or organized into a hierarchy. Dispositional theorist divide personal dispositions into three categories: Cardinal Traits are traits so dominant that a person's entire life revolves around it. Central Traits are the general characteristics that form the basic foundations of personality. These central traits, while not as dominating as cardinal traits, are the major characteristics you might use to describe another person. Terms such as *intelligent*, *honest*, *shy* and *anxious* are considered central traits. Secondary Traits are characteristics

that are exhibited in specific situations, while third traits are more easily modified than central traits.

Dispositions are presumed to be relatively enduring and stable, producing some degree of consistency in behaviors across times and circumstances. Most dispositional psychologist conceptualizes an individual's enduring dispositions as permanent, inherent elements of personality and distinguishes them from temporary conditions, or states. States result from transient situations or conditions like illness, fatigue, or sudden changes in life circumstances. These secondary traits are often linked to risky behavior because of the impact that changes in the environment have on it. As such, individuals for which high extraversion, openness to experience, and neuroticism coupled with low conscientiousness and agreeableness are secondary traits they are likely to be prone to accident and high risky behavior especially when they are driving.

2.2.3 Big Five Model

The "Big Five" personality traits are five broad factors of personality dimensions developed through lexical analysis. This is the rational and statistical analysis of words related to personality as found in natural language dictionaries. The traits are also referred to as the "Five Factor Model". The model is considered to be the most comprehensive empirical or data-driven enquiry into personality. The first public mention of the model was in 1933, by Thurston.

The five factors are: Openness, Conscientiousness, Extraversion, Agreeableness and Neuroticism [OCEAN] which can be summarized as follow: Openness is a general appreciation for art, emotion, adventure, unusual ideas, imagination, curiosity, and

variety of experience. The trait distinguishes imaginative people from down – to – earth and conventional people. People who are open to experience are intellectually curious, appreciative of art, and more aware of their feelings. They are more likely to hold unconventional beliefs. People with low scores on openness tend to have more conventional, traditional interests. They prefer the plain, forward and obvious over the complex, ambiguous, and subtly. They are conservative and resistant to change.

Conscientiousness is a tendency to show self-discipline, act dutifully, and aim for achievement. The trait shows a preference for planned rather than spontaneous behaviour. It influences the way in which people control, regulate and direct their impulses, this can explain why a cyclist will choose to act either spontaneously or rationally while riding. It can help in measuring one's perceived vulnerability. Conscientiousness includes the factor known as need for achievement. The benefits of high conscientiousness are obvious. Conscientious individuals avoid trouble and achieve high levels of success through purposeful planning and persistence.

Extraversion or extroversion is characterized by positive emotions, urgency, and the tendency to seek out stimulation in the company of others. The traits are marked by pronounced engagement with the external world. Extraverts enjoy being with people, and are often perceived as full of energy. They tend to be enthusiastic, in groups they like to talk, assert themselves, and draw attention to themselves. Introverts lack the exuberance, energy, and activity levels of extraverts. They tend to be quiet, low-key, deliberate, and less involved in the social world. Their lack of social involvement should not be interpreted as shyness or depression.

Agreeableness is a tendency to be compassionate and cooperative rather than suspicious and antagonistic towards others. The trait reflects individual differences in concern for social harmony. For example, agreeable individuals value getting along with others, they are generally considerate, friendly, generous, helpful, and willing to compromise their interests with others. Agreeable people also have an optimistic view of human nature; they believe people are basically honest, decent, and trustworthy. Disagreeable individuals place self-interest above getting along with others. They are generally unconcerned with others' well-being and are less likely to extend themselves for other people; sometimes their skepticism about others' motives can cause them to be suspicious, unfriendly and uncooperative.

Neuroticism is the tendency to experience negative emotions, such as anger, anxiety, or depression; it is sometimes called emotional instability. Those who score high in neuroticism are emotionally active and vulnerable to stress. They are more likely to interpret ordinary situations as threatening, and minor frustrations as hopelessly difficult. Their negative emotional reactions tend to persist for unusually long periods of time, which means they are often in a bad mood. These problems in emotional regulation can diminish neurotic's ability to think clearly, make decisions, and cope effectively with stress. At the other end of the scale, individuals who score low in neuroticism are less easily upset and are less emotionally active. They tend to be calm, emotionally stable, and free from persistent negative feelings. Freedom from negative feelings does not mean that low scores experience a lot of positive feelings. Frequency of positive emotions is a component of the extraversion domain.

The Big Five personality traits have been found to define an individual's personality traits which are the driving force of an individual exhibited behaviour. The theory argue that the five core personality traits, consisting of Openness to experience, Conscientiousness, Extraversion, Agreeableness and Neuroticism, contain six additional underlying traits within each factor (Costa and McCrae 1992; Somer and Goldberg 1999). This theory suggests that the drivers' behaviour is seen as reflecting a balance between personal motives (for example, thrills, the desire for speed or position in the traffic stream) and the subjective risk of crash involvement.

The theory opined that drivers in general do not perceive any risk of crash involvement due to vulnerability of their personality (extraversion, low conscientiousness and high openness to experience). This lack of subjective risk of accident involvement allows drivers to fulfill a variety of other needs thus leading to high risky driving and involvement in road crashes due to their poor perceptions informed by their personality. Another approach to the concept of subjective risk has different implications for driver risk taking. According to Santos (1995), psychological variables (such as personality) are associated with high level of inter-individual variability, which can have a significant impact on the driving behaviour. Personality traits seem to be good predictors of crash-related conditions, aggressive risky driving, driving with anger expression and risky driving violations

2.2.3a Application Big Five Model to the study : According to Atkinson's, Smith's, Bem's, and Nolen-Hoeksema's (1996) views personality is represented by the distinctive and specific patterns of thoughts, feelings and behaviours that identifies the interaction

with the physical and social environment .The researchers concluded that there are five dimensions of personality. Neuroticism includes anxieties, worries, anger issues, uncontrolled actions, insecurities and depression. People with neurotic tendencies, complain of at least one of many psychosomatic indications, such as chronic fatigue, headaches, insomnia, vision disability or anorexia. For this reason, neurotics can be described as leaning towards negative emotions, especially anxiety, depression and anger which makes them prone to risky driving behavior and accidents. On the contrary people with high levels of emotional stability tend to be very temperate, relaxed, and resistant even under stress conditions. Low emotional stability, sometimes called neurosis (meaning high level of neuroticism), and often affects personality adversely. Those with a low emotional stability are more likely to experience psychological distress (for example, depression, anxiety, anger, and insecurity), unrealistic beliefs, and poor coping strategy.

Empirical evidence in favour of the relation between emotional stability and risky driving: drivers who have a higher score on the neuroticism scale are easily angered and insecure and they have an increased risk of driving behavior (Lajunen,2001). Extroverted people on the other hand, tend to engage in frequent activities, positive emotions, entrepreneurship and social behaviors. They are adventurous, active, talkative, cheerful, optimistic and energetic, enjoy fun and action. Extraversion is characterized by sociability, assertiveness, impulsivity, and activity. There is evidence that extraversion is positively associated with traffic accidents (Lajunen, 2001), road errors (Verwey and Zaidel, 2000) and violations of traffic rules. Theoretically, extraversion should be related to risky driving behaviour and accident proneness because it is marked by active and sometimes impulsive behaviors. Given that risky driving behaviour and accident

prone behaviors appear to be impulsive by nature, we expect that drivers with a high level of extraversion to be more prone to aggressive behavior while driving.

Openness to experience is a trait in people characterized by creativity, imagination, liberalism in thoughts and they embrace new perspectives and multi-dimensional ways of thinking and mental curiosity. The opening is marked by traits such as imagination, culture, curiosity, originality, open mindedness, intelligence, and artistic sensibility. Although this factor has received the least attention of the Big Five in literature, there is some evidence that might be relevant to driving behavior. It postulates that an egocentric mentality often associated with aggression in traffic is lower among more sensitive, broad-minded, and tolerant people (for example, those with a large opening). Therefore, openness to experience may increase the likelihood that a driver will make more realistic assumptions and relies more on situational factors. Assignment of situational "apologies" to other drivers implies that errors are caused by circumstances that are, at least partially, beyond their control, which in turn is less likely to rely on hostile reactions.

An agreeable appearance represents a friendly, respectful and modest behavior, which means agreeableness includes basic features such as honesty, sacrifice, harmony, modesty, high emotions, trust and friendship. It is associated with physical and emotional care and inclination towards care. Therefore, agreeable people can be described as sincere, intimate, friendly and tolerant.

Agreeableness is associated with being courteous, flexible, reliable, kind, cooperate, forgiving and tolerant. This is the dimension of the BFM associated with maintaining positive interpersonal relations. It should be linked to risky driving behaviour and accident proneness as extremely pleasant individuals would be less likely to behave in a

hostile manner, even when challenged, as they seek to enhance cooperation and avoid negative emotions.

The construct Conscientiousness covers efficiency, conscientiousness and self-discipline. These include personnel management, self-discipline, debate and basic characteristics of competence. Features most commonly associated with conscientiousness include reliability, care, thoroughness, responsibility, organization, planning, hard work, guidance, achievement. Similar results were reported for thoroughness, a secondary variable that is also part of the conscientiousness spectrum. Moreover, they are more likely to comply with driving rules, do not engage in risky situations, avoid dangerous situations and adhere to standards of performance (Arthur and Graziano, 1996) through self-regulating behavior.

Traffic behavior theories predict that behaviors related to risky driving behaviour and accident proneness (for example, excessive lane changes, speeding) are associated with outcomes such as near misses, physical injuries, stress, and violations of rules. Personality traits can affect behavior and can be associated with many aspects. In this model, degrees of risk-taking are a function of self-regulatory aspects of personality.

2.4.0 OVERVIEW OF TRANSPORT POLICY AND TREND OF ACCIDENT RATE IN NIGERIA

Transport is the pilot on which all development and other economic activities revolve. The collapse of the transport sector, therefore, would affect other economic activities. Transportation is an integral part of the functioning of any society, It exhibit a very close relationship to the style of life, the range, the location of productive, leisure

activities, goods and services which are available for consumption. No society can urbanize, industrialize and advance the living standard of its people without the aid of transport for the activity center, proximity to place of work, relation, and socializing, shopping, medical care. Transport is an important part of everyday life and in consequence; a large and expansive literature has grown over the years on various aspects of transport. One of the characteristics of road transport is its ability to give door-to-door facility and it acts as feeder to all the other modes of transport.

According to Oni (2004) Transport is a key element in the social and economic development of any nation. Therefore, Nigeria's transport policy has two major thrusts, namely: that transport services are adequate to meet the social and economic needs of the country and to provide an effective instrument of national development; and that the transport system ensures the most efficient use of resources within the transport sector and a sustained improvement of the sector's productivity.

Therefore, there is need to develop a national transport policy that is responsive to the needs of the country and its people. According to Oyesiku (2004) the prime of such a policy is the provision of an affordable adequate and efficient transport system. The policy of the federal republic of Nigeria, as contained in its National Economic Empowerment and Development strategy (NEEDS), is to increase the participation of the private sector and private initiative in the national economy. Under this arrangement, the private sector "will be executor, investor and manager of businesses, while the government will play the role of enabler, facilitator and regulator, helping the private sector to grow, create job and general wealth". The national transport policy therefore acknowledges this need for introduction of the discipline of market economy into the

country's transport sector, in order to attract private investment initiative and as far as possible, to transfer responsibilities for the functioning of the transport system from government to the private sector.

This does not mean the abdication of government responsibilities, but rather a focus on the role of the government leading to a true public – private sector partnership (PPP), with both the private and public sector performing their proper function; this is the main goal of the current national transport policy for Nigeria. The fundamental goals of Nigeria's transport policy are to develop an adequate, affordable, safe; environmentally sound and efficient transport system in the context of a progressive and competitive market economy.

Previous transport policy had also hampered formulation, development, regulation, control and implementation of urban transport guidelines. These have somewhat made the concept of the policy difficult and the appraisal of the policy document impossible before implementation. Moreover, the process of formulation of the policy alienates the stakeholders, particularly private sector operators of the transport system as well as the ordinary transport users or riders. The fact that there was little consultation with stakeholders made the previous efforts of putting together national transport policy an exercise destined for the shelves. Closely associated with the problem of inadequate data and poor consultation, the approaches of government in the evolution of transport policy are the inability of even government stated policy statement to change overtime. A good regulatory and control system, like a transport system must be subjected to modification and review. Despite so much in the literature of urban transportation development, even in several developing countries, virtually all – urban

centers in Nigeria do not have an urban transport development plan. Lagos has one but this is not updated.

As a result of these constraints, although the potential effect of urban transport policy is great, efforts to put in place urban transportation policy have relatively little effect on the provision, use and rider ship of urban transportation services and therefore, poor qualities of the services and welfare of the people. The issues in urban transport policy in Nigeria as being discussed call for government intervention in setting the rules guiding urban transport system in the country. These issues do not support government direct participation in the provision of services or setting out rigid guidelines for the operation and management of urban transportation systems in the country. Indeed, the issues are not the basis of arguments for regulation or deregulation but articulating urban transportation policy that would guide efficient, adequate safe, comfortable and cost effective urban transportation system.

Nigeria was ranked 191 out of 192 countries in the world with unsaved roads with 162 death rates per 100,000 populations from road traffic accident. According to World Health Organization (WHO, 2007) estimate over 1.3million people are killed annually in road accident while over 50million people sustain different degrees of injuries from crashes.

The chief executive of the Federal Road Safety Commission (FRSC 2012), Mr. Osita Chidoka disclose that over 80 percent of above figure occurs in the developing countries with Africa accounting for the highest death rate. He went further to say that WHO predicted that if nothing is done by the countries to stem the tide, death by Road Traffic Accident would increase by 65percent by the year 2015/2020 overtaking malaria and tuberculosis.

According to Federal Road Safety Corps reports of 2007; the following months (May, June December and September) had the highest number of persons involved in road accidents and number of persons injured compare to other months of the year , in the year 2008 the months of February, March, July, August and December recorded the highest number of persons involved in accidents, number of serious cases and number of persons injured compare to other months of the year. 2009 showed that January, November and December reported highest number of persons involved in the accident, number of serious cases, and number of persons injured and number of persons killed compare to other months in the year.

Furthermore, in the year 2010 accident rate showed that the months of March, June, November and December recorded the highest number of persons involved in the accident, number of serious cases and number of persons injured and number of persons killed compare to other months in the year. The highest number of persons involved in accident and number of serious cases and persons injured in the year 2011 occurred in November and December compare to other months of the year.

No matter how one drives, there is always a chance that an accident might happen, no one can predict when it will occur. In other words, road accident is unpredictable it usually occurs at any given time with or without warning signal(s) to motorist and other road users. However, accidents do not just happen, every accident has a cause, the causes may be external to the individual, it may be within or it may result from both sources. But with broad based knowledge of road safety, the worst road accident can be prevented or

avoided. According to Oyeyemi (2006) the causes of road traffic accident was classified into four major factors namely:

Human factors: Road user is the most capable factor of causing accident and it often results from unsafe interaction with other road user or any other causative agent of road accidents. Human factors constituted about 80 percent of the cause of road traffic accidents as recorded in FRSC Data sheet every year, Onakomaiya, (1988) agreed that a greater percentage of accidents is attributable to human factors and argued that highways and vehicles as mere passive agents of mobility. The revised Highway Code Osita(2012) highlighted some specific avoidable causes of road accident which includes drivers, pedestrians and passengers:

Mechanical Factor: Mechanical factor is the issue of the road worthiness of vehicle. This has to do with the Mechanical fitness of the Vehicle. If all of the vehicle plying Nigerian roads especially the commercial ones, are subjected to Potential Mechanical Defect Test (PMDF), the percentage that will contravene existing rules and regulations will be incredible and unbelievable as majority will rank as junks. Oyeyemi (2003) observed that: “The abundance of mechanically defective vehicle is common sights on our road”.

According to Oyeyemi (2009), “Many of these vehicle lack minimum vehicle safety standards”. However, it will be difficult to shy away from the fact that the popularity of rickety vehicles and the general use of imported second hand vehicles romantically labeled as tokunbo are not unconnected with the more often than not, mechanical induced accidents are incidental to human errors or acts of omission or commission. To keep a vehicle in good mechanical condition, some of the devices that require particular attention are: brakes, steering mechanism, horn and mirrors.

Road Factor: Road factor concerns road design, construction, maintenance and usage as well as complementary road infrastructure and street furniture. In most parts of Nigeria, the roads constitute serious hazards to road users. Road infrastructure and furniture like road signs and side rails are conspicuously absent. It was until the current road maintenance drive embarked upon by the Federal Ministry of Work (FMW) through the establishment of the Federal Road Maintenance Agency (FERMA), maintenance of the very few roads that were in good shape used to be an abandoned issue. However, the importance of ergonomic design and construction of road to traffic safety cannot be over-emphasized as the physical condition of the road constitutes important psychological factors in safe driving.

As a matter of fact, there is no justification for the serpentine road network that stretches all over the place especially in the south west. It is even more disgusting that road constructed in Nigeria several decades ago are more “Modern” than recently constructed ones. A classic example of poorly constructed road is the Ilesa/Ile-Ife/Ibadan dual carriage expressway with its major intersections, Ilesa/Osu and Ile-Ife town road/Ile-Ife by pass, as inherent death traps. Disappointedly, it is difficult to compare any of these two newly constructed intersections with either the Lagos Bye Pass/Challenge or Lagos/Ojo/Gate/Iwo Road flyover intersection, both in Ibadan.

A good road, no doubt, is a prerequisite to good driving, but a bad road itself will not cause accident if the drivers are conscious of the state of the road. Adeyemi (2003), in an article “Catching them young for safer roads” in the PUNCH newspaper on November 25, 2003 observed that, “it is unarguable that roads are in bad shape, traffic signs are not

conspicuously displayed on the highways (excuses often given by errant drivers) but all these will be secondary if the human mind is constantly is altered or alert to the fact that these deficiencies are always preset and there is a need to make the best advantage of a worst circumstance.”

Environmental Factor: The environmental Factor consists principally of the weather and climate condition. Torrential rain falls and extreme sunshine subject road to early deterioration. “Driving becomes much more difficult and hazardous when visibility is blurred by weather conditions such as rain, moist, fog, harmatan dust or other related factors” (FRSC, 2009).

Road will be become slippery when they are wet and become impassable if there is flood. Other factors that may cause environmental hazards include indiscriminate dumping and abandoning of wrecked vehicles, wrongly-packed broken vehicles, trees and poles, animal herding abandoned stones, woods or other hard objects used for raising vehicles or as chocks when motorists change deflated tires on the road. These objects often cause accidents because other vehicles can run into them of particular concern are mangled vehicles. All these bad sight can distract attention from concentration which is the pivot of driving. Generally, accidents can be influence by any adverse environmental factor.

2.5.0 CLARIFICATION OF KEY CONCEPTS

2.5.1 Concept of Risky Driving Behaviour: Driving behaviour may comprise ;(1) exposure (for instance, duration of driving), (2) patterns, or when and where, and (3) habits for example speed, common errors and so on). Exposure is commonly reported as distance (km) driven per week (for example, Huebner, Porter and Marshall, 2006; Johnson, 2003, Marshall et al. 2007) or year (for example, Carr, Flood, Steger-May, Schechtman and Binder,2006; Gallo, Reebok and Lesikar, 1999, Ozkan, Lajunen and Summala, 2006), frequency of trips per day for example Collia, Sharp and Giesbrecht, 2003, O’Fallon and Sullivan, 2003) or week (for example Gallo et al.,1999, Johnson, 2003) and length of trips, such as km per trip (for example ,Marshall et al., 2007).

Furthermore, exposure is widely cited when discussing crash risk and driver safety (For example, Bedard et al., 2001; Evans 1991; Hakamies-Blomqvist and Wahlstrom, 1998, Margolis et al., 2002, Maycock, Lockwood and Lester, 1991) as well as self – regulation (for example, Burns, 1999.Cox 1989, McGhee, 1983; Raitanen, Tormakangas, Mollenkopf and Marcellini, 2003). Some researchers (for example Hildebrand, Gordon and Hanson, 2004) define exposure in terms of encounters of risky situations (for example number of left hand turns); however, behaviour that considers situation (for instance, When and where) can also be classified in terms of ‘patterns’.

Night time driving is more hazardous than day time driving for all age groups of drivers but has marked impact on the crash involvement of teen drivers (Rice, Peek-Asa and Kraus, 2003). Teen drivers have diurnal crash patterns that are distinct from those of adults, for teen driver crashes peak at 7am and remain elevated until 9am. Fatal crashes have the same morning and afternoon spikes but the numbers of fatal crashes remain

elevated until midnight, after which they descend slowly to a low level at 4am for all drivers, the risk of motor-vehicle crash increases on the weekend (Schwing and Kamerud, 1988).

Driving behaviour are influenced by many factors including the personal levels of knowledge, awareness, skills, experiences, the conditions found in the motor vehicle and the various conditions of the community in which drivers live. Individual characteristics that have been found to be related to motor vehicle morbidity and mortality among drivers include race, age, gender, cognition, driving experience and level of education. Other risk factors for motor vehicle crashes among drivers include current bio-physiological condition (for example motor skills, sleep deprivation and psychiatric/ neurological status), mental status (for example, mood and thoughts feelings) and behavioural disposition (for example, risk taking and impulsivity) that the individual brings to the situation. There is growing recognition that drivers who, engage in risk behaviours often participate in multiple types of risk behaviours, referred to as clustering or co-occurrence of risky behaviours, shares common underlying cause such as behavioural, biological, family and neighborhood factors.

Research indicates that drink drivers are less likely than other drivers to adopt safe driving behaviours, and are more likely to be risk taking drivers, even when sober than non-drink drivers. Higher levels of drink drivers are associated with other high-risk driving behaviors including speeding, riding with a drink driver and aggressive driving {Bingham and Shope 2004, Donovan 1993, Everetta et al 1999, McMillen et al 1992, Patil et al 2006}.

In road traffic, risk is a function of four elements the first is the exposure – the amount of movement, or travel within the system by different users or a given population density. The second is the underlying probability of a crash, given a particular exposure. The third is the probability of injury given a crash. The fourth element is the outcome of the injury. Risk can be explained by human error, kinetic energy, tolerance of the human body and post-crash care. Road traffic injury should be considered alongside heart disease, cancer and stroke as a public health problem that responds well to intervention and much of it can be prevented from occurring.

Talking on a cell phone while driving - It seems as if this practice has become epidemic. People are using their driving time as an opportunity to carry on completely unnecessary conversations with family and friends. When engaged in cell phone conversation, it has been shown that drivers have slower reaction times and are more likely to miss seeing important obstacles in their rural ahead. It appears that the simple act of carrying on a distracting conversation is enough to increase the risk of an accident. The following are usually noted in drivers: applying make-up, eating lunch behind the wheel, reading while driving' there are people who actually read when driving.

Trying To Be A Tough Guy: There are people in this world who quite convivial until they get behind the wheel of a car. Shielded by that tinted glass, they feel invincible and imperious. When someone inadvertently pulls in front of them, their ego takes over and emit a barrage of verbal abuse and hand gesture directed through the car window.

Among human factors in accident causation are broad factors leading to error, they include the following; overload and inappropriate activities

Overloading: Worker's capacity/natural ability, training, state of mind, fatigue, stress, physical condition .Environmental factor: noise, climate, lighting, destructions .Internal factor: personal problem, emotional stress, worries .Situational factors: level of risk, unclear instructions, novelty

Inappropriate Activities: Ignores a suspected hazard, disregards established safety device, performing tasks without requisite training, misjudging the degree of risk.

Human factors appear in the literature as being the most prevalent contributing factors of road traffic crashes. This includes both driving behaviours (for example speeding, drinking and driving, traffic law violations) and impaired skill (for example inattention, fatigue, physical disabilities, impaired sensory perception and so on (Bingham and Shope 2004, Donovan 1993, Everetta et al 1999, McMillen et al 1992, Patil et al 2006

2.5.2 Cost of Risky Driving Behaviour :Most traffic fatalities are caused by risky traffic behaviour, such as drunk driving, non-use of safety belts or child occupant restraints (Satcher, 2001), speeding (Shinar et al, 2001, Golias and Karlaftis 2002, Mesken et al, 2002), not making oneself visible at night and in poor visibility (European Transport Safety Council, 2006), reckless riding on bicycles (Wesson et al, 2000) or motorbike (Busters et al 2005, Lace and Godldstein, 2005), and unsafe crossing of roads (Tabibi and Pfeffer, 2003). Although drunk driving has decreased in many countries during the past twenty years, alcohol consumption is still one of the main factors in road traffic accidents (European Transport Safety Council, 2001)

In United States approximately 40% of all traffic fatalities in 2001-2002 (Chou et al, 2006) and in Estonia one fifty of all traffic fatalities in 2001-2005 (Maanteeamet, 2006a; and 2006 b) were alcohol related.

Road Traffic crash is a sad and unfortunate event it is sad because of the human and material losses and unfortunate because it is preventable. The worry here is that while the pains of accident are known, nobody has accurately estimated its cost or fashioned a means of arresting and reversing the ugly trend. The ever-increasing pressure on the road transport mode is a mind-bugging source of sudden death, which throws a number of families into grief in our country .Statistics from World Health Organization (WHO) shows that an estimated 1.18million people were killed by road crashes in 2002 while about 20 to 50 million were injured and about 5million were disabled for life ,if the current trend continues by 2020, the annual number of deaths and disabilities from road traffic injuries would have risen by more than 60% to make road death come third on WHO' list of contributors to the global burden of diseases and injury.

The global cost of road accidents and resultant from injuries amounted to \$518billion, developing countries accounted for \$65billion of that amount, which was more than what they receive in official development assistance ,The majority of motor vehicles were operated in the developed world, and it might be expected that most fatalities would occur .The statistics from WHO however showed that low and middle – income countries accounted for about 85% of deaths and disproportionate high percentage of disability globally. Around the world, injuries were among the leading causes of death of people aged 15-44 .The social cost is incalculable the loss of

breadwinners and the long –term care for people disable in road traffic accident has driven many families into poverty, particularly in developing countries.

Nigeria, according to WHO has a total population of 135.3 million and a GNP per capital of \$1, 085, has a life expectancy of 45 and 46 years for male female respectively .Out of these few years ,the citizen can at best hope to live healthy life for 41.3 and 41.8 years for male and female respectively,197 out of every 1000 children born can die during childhood while the adult mortality rate per 1000 average 496 .The income per capital is \$51 and the total health expenditure as percentage of GDP is 5.0 percent. Clearly Nigeria is not so healthy.

The contribution of road crash to this statistics in Nigeria is startling .Between year 2000 and 2005, a total of 65,248 vehicles were involved in road traffic accidents, with buses and other mini transport means accounting for 51.6% and articulated vehicles accounting for 16.8% while the remaining 31.6 % are attributed to cars.

2.5.3 Concept of Accident Proneness : Historically, the concept of accident proneness originated in the work of Greenwood and Woods (1919).They investigated accidents among workers in a Munitions factory in Britain during the First World War .These early investigators examined and compared the distribution of accidents with alternate hypothetical distributions which were based on different assumptions about the causes of accidents .If the chance of having an accident is the same for each individual, then the distribution produced would be a Poisson distribution. However, if the accident probability was unequal for different individuals, then another distribution such as the negative binomial could be expected (McKenna, 1983). Accidents were found to be unevenly distributed with a relatively small proportion of the workers having most of the

accidents. They went on to hypothesise that personality differences could account for this distorted distribution. However, such a conclusion was not justified on the basis of the evidence presented (Henderson, 1971). For instance no personality tests had been performed. The term accident proneness appears to have been coined by Farmer and Chambers (1939, cited in Henderson, 1971).who used the term to refer only to personal factors. Farmer and Chambers (1939) also found an uneven distribution of accidents with the use of psychological testing they claimed that had established the existence of accident proneness.

Henderson (1971) reports, however that these tests were of doubtful validity. Only one proved to be significantly related to accidents. This was not a test of personality differences between crash repeaters and non-crash involved drivers. A consistent definition of accident proneness has not been employed by many researchers in the area (McKenna, 1983, Shaw and Sicheal, 1971).Thus; it is not surprising that several approaches to accident proneness have been developed. The first treats accident proneness as a single personality trait or type, while another considers it as a multiple series of characteristics (McKenna, 1983) .Other researchers have described accident proneness very broadly as a “tendency to have accidents” (Shaw and Sichel, 1971). This tendency is regarded as a global characteristic, generalizing across different environments. If a person is to be considered accident prone “he must be susceptible to accidents under all circumstances” or at all times” (Shaw and Sichel, 1971).Wong and Hobbs (1949 cited in McKenna, 1983) concluded that “accident tendency was a lifelong characteristic and that it appears to invade all aspects of life”. Finally, several authors have postulated that accident proneness refers to innate, unchanging characteristics of the individual (Hale and

Hale, 1972, cited in McKenna, 1983). However, this latter view must be considered as an extremely controversial position.

Shaw and Sichel (1971) contend that whatever the definition ascribed to accident proneness the basic underlying principle which all interpretations hold in common is that “even when exposed to the same conditions some people are inherently more likely to have accidents than others. People differ in their propensity for accidents”

In general the concept of accident proneness has fallen from favour and the concept has been criticized on statistical grounds (McKenna, 1982; 1983) McKenna (1983) reports that the negative binomial fit may be derived from assumptions which do not involve risk of having an accident. Some individuals in any given group would be expected to have more accidents purely by chance (Joseph and Schwartz, 1975, cited in Noyes, 1985). The interpretation of negative binomial fit as evidence for accident proneness requires the absolute control of non-personal factors such as exposure to accident risk and bias in accident reporting. Such a distribution could also be obtained if some people are more exposed to risk than others (McKenna, 1983).

However, the concept of accident proneness (or its equivalent injury proneness, liability to accidents and injuries) remains subject of much controversy, debate and conceptual confusion (McKenna, 1983). An often mentioned problem is that instead of attributing accident proneness to certain individual, it would be better to blame consider a shortcoming in the health and safety regulations in the workplace (Green, 1991). In this respect it has acted as a barrier in the development of preventive occupational health and safety principles and practices (Sass and Crook, 1981). Still, the concept of a personal liability to accidents has remained an active component of medical knowledge although a

large variety of definition of accident proneness was used in the past. It is striking that since a discussion about the concept in 1992 in the Journal of the Royal Society of Medicine (Engel, 1991; Green, 1991; Hindmarch, 1991) the term accident proneness was found in the title of only one article with empirically data (Baker et al., 1995). Instead, words like repetitive injuries, recurrent injuries or injury liability are used. In this respect, a clear distinction can be made between accident liabilities, which refers to both personal and environmental factors determining accident rate, and accident proneness, which refers to personal factors only (Beracki, 1976).

2.5.4 Socio-Economic Status, Location and Risky Driving Behaviour

Several studies have shown that people from less-privileged socioeconomic groups are at greater risk of injury from all causes, including road crashes. In the case of road crashes, the explanation may lie in their greater exposure to risk. In a study by John (2002) found that 27% of commuters with no formal education travelled on foot, 55% used buses or minibuses and only 8% used private cars. By contrast, 81% of people with a secondary-level education travelled in private cars, 19% used buses and none walked.

In general people living in urban areas are at greater risk of being involved in road crashes, but people living in rural areas are more likely to be killed or seriously injured if they are involved in crashes. One reason is that motor vehicles tend to travel faster in rural areas. In many low-income and middle-income countries, many people are exposed to new risks when new highways are built through their communities.

2.5.5 Review of Personality and Risk-Taking in Traffic

Amongst the personality traits, risky behaviour is most consistently associated with impulsivity. The relationship between impulsivity and traffic behaviour has been studied since the late 1980s (Jonah, 1997) but not all of the accumulated evidence is consistent. Impulsivity is defined as a scope of various tendencies including rapid and thoughtless action (Dickman, 1993, Barratt, 1993), risk-taking (Eysenck, 1993), low self-control and inability to hold back one's desires (Buss et al., 1973; Costa and McCrae, 1989).

In the context of everyday life, the approach of Discman (1990), which differentiates dysfunctional impulsivity (tendency to act with less fore thought than most people which leads the subject to difficulties) and functional impulsivity (tendency to act with little forethought when such a style is optional), may bear particular significance. Jonah (1997) reviewed studies done in the late 1980s and the early 1990s on the relationship between sensation seeking and risky driving (for example, driving while impaired, speeding, following too closely, not wearing a seat belt), as well as its consequences (for example, collisions and violations).

Risk-taking in driving habits has shown a positive correlation with the Aggression-Hostility trait according to the Zuckerman-Kuhlman personality questionnaire (Zuckerman and Kuhlman, 2000) and with Anger (Parker et. al. 2002; Deffenbacher et al, 2003)

2.5.6 Alcohol Use and Accident Proneness

Although drinking would appear to increase the risk of being involved in a crash, it is not a guarantee that a crash will take place (Gusfield, 1985). Gusfield argues that by “singling out alcohol involvement as the cause of crashes, we leave unstated and untested hypothesis that without the presence of alcohol the crash would not have occurred and that alcohol is the only element in the causal process that is capable of being changed’ .While the fundamental conclusion of the overwhelming majority of research is not being challenged that for every group or set of conditions increased alcohol use increases the risk of crashes (Gusfield, 1985), A number of studies have investigated the contention that it is not alcohol alone which necessarily causes crashes, but alcohol in combination with other factors such as personality and social background.

Zylman (1975) in a literature review the influence of alcohol in traffic crashes argues that only 30 percent rather than 50 percent of all crashes involve alcohol and that relatively few alcoholics are high risk drivers. He argues that it is not alcohol alone that leads to crashes but a combination of personality characteristics (alienation, hostility, aggression, and /or transient traumatic experiences) and alcohol .Zylman (1974, cited in Zylman, 1975) suggests that 70 percent of crash cases, personality, situational, or environmental factors are more important than alcohol, even though they may have been drinking . It should be noted at this point that while this conclusion and those to follow may have some intuitive appeal, they are not based on sound conclusive evidence.

2.6 EMPIRICAL REVIEW OF RELEVANT LITERATURE

2.6.1. Gender and Risky Driving Behaviour

Gender significantly influences risky driving behavior among the drivers, especially males, often use vehicles to show-off, to attract attention or impress members of the opposite sex, to obtain excitement and to display competitive courage among young women (Iram and Taubman, Arnett et al., 1997; Jonah, 1997; Kohler, 1996). Male participants in these studies significantly reported higher risky driving behaviour than the female counterpart. These findings is similar to that of Özkan and Lajunen (2006) that revealed being male is significantly associated with more Highway Code violations. Moreover, men report more aggressive driving behavior (Deffenbacher et al., 2003). According to Barros and Loureiro (1997), infringements of road traffic laws are usually committed by male individuals who have had a driving license for more than two years or less than six months; drive an average of 200 km a week and who have not been fined for road traffic offenses in the last five years. Males behave in a riskier manner than females and these risky types of behaviour tend to decrease with age (Peck, 1993). Moreover, the meta-analytical by Bogg and Roberts (2004) showed that male drivers under 30 years of age exhibited lower self-control levels ($r = -.27$) than older male drivers ($r = -.13$). It seems that deviant driving styles are associated with being male and young (Elander et al., 1993).

Males consistently exhibit greater risky driving, and road trauma involvement, compared with females (Job, 1990b; Prabhakar et al., 1996). For example, Harre, Field & Kirkwood (1996) found that males were significantly more likely than females to report engaging in speeding, drink-driving, and breaking rules associated with being on a

restricted licence. Male drivers have also been observed to engage in greater speeding behaviour (Wasielewski, 1984), and greater tailgating behaviour (Evans and Wasielewski, 1983), compared to female drivers. Nonetheless, some researchers suggest that the risky driving behavior of females is becoming increasingly similar to that of male drivers (Moore, 1994). Sensation seeking and trait aggressiveness were found to be strongly related to risk taking in general and to reckless driving in particular among young men and less among young women (Arnett et al., 1997; Jonah, 1997; Kohler, 1996).

2.6.2 Age and Risky Driving Behaviour

The driving literature reveals that motivations like competitiveness, sense of power and control, or just pursuing sensual pleasure may impinge on the way one drives and may influence a person's decision to drive recklessly (Evans, 1991). Vehicles are often used as an outlet for independence, emotional expression, rebelliousness, and to satisfy peer-acceptance needs of young drivers (Jessor, 1987).

In particular, young drivers are more likely to engage in risky driving compared with older drivers (Jonah, 1986; Job, 1999; Williams, 1998; Cameron, 1985; Prabhakar et al, 1996). These are the same driving errors commonly identified for young drivers of cars (McKnight and McKnight, 2000, 2003). Thus, with respect to demographic and employment status, accident incidence has been found to decline with a bus driver's age (Dorn and afWählberg, 2008; Greiner, Krause, Ragland, & Fisher, 1998; Jovanis et al., 1991; Zegeer et al., 1993) and driving experience (Blom, Pokorny, & van Leeuwen, 1987).

2.6.3 Education and Risky Driving Behaviour

Professional driving is an occupation that traditionally attracted a greater proportion of males (Tse et al. 2006), while some previous studies concerning car driving concluded that a driver's educational levels are associated with accident risk (Hemenway Solnick, 1993; Shinar, 1993; Shinar, Schechtman, Compton, 2001). Begg, Langley, Stephenson (2003) investigated factors that predicted persistent driving after drinking, persistent unsafe driving after drinking, and persistent cannabis use and driving among young adults. They found that mental health measures (substance use, cannabis dependence, alcohol dependence, depression); anti-social behavior (juvenile arrest, aggressive behaviour, court convictions); early driving behaviour and experiences (car and motorcycle licences, traffic crashes) and gender predicted risky driving behaviour. The results showed that males who persisted in driving after drinking were more likely than the other males to have some school academic qualifications and to be employed at age 26.

The study of Rowe, Maughan, Gregory and Eley (2013) who found that attitudes became riskier more accidents proneness obtained the more training and/or driving experience was acquired between these two time points. Drivers who received certificate in driving were more likely to endorse risky driving behaviours than either non-drivers or learner drivers in 2004. Riskier attitudes were associated with having held a full licence for longer, having clocked up more driving miles, and having committed more speeding violations.

2.6.4 Gender and accident Proneness

Kennard (2014) reviewed studies that showed that most men know that on average, will live shorter lives than women. What is less well known is the fact that accidents and violence are one of the major contributors to early deaths and disabilities. Young men in particular are over represented in the deaths and accidents statistics, probably because they are most likely to participate in risky behaviours. Boys are twice as likely to die as girls in play-related accidents or by falling out of windows. As adults men are three times as likely to die from injuries as women evidence from several countries have shown that men are between two and five times as likely to be admitted to hospital as a result of injuries. Young men are more likely to have serious accidents than women of the same age because they are more prone to sudden breaking and driving for extended periods without taking a rest. When it comes to young drivers, risky and aggressive driving appears to be the dominant human factor that places them at risk (Reason et al., 1990). Additional variables include the fact that they are inexperienced but tend to over-estimate their driving skills while underestimating danger (Fisher et al., 2002) and that they tend to drive lower quality vehicles (Williams et al., 2006).

It has been found that young drivers believe they are at lower risk to become involved in an accident compared to older adults and age-mates, when in fact their chances are much higher compared to older drivers. At the same time, they overestimate their driving ability compared to what is actually found to be the case in laboratory driving simulations (for example, McKenna and Crick, 1991; Finn and Bragg, 1986; Brown, 1982).

Studies comparing men and women in general tend to support this since they usually fail to find a difference (Joint, 1995; Lajunen, et al., 1998; McGarva and Steiner, 2000). The same applied to research looking at mild aggression such as horn honking and fist shaking (Hennessy and Wiesenthal, 1999, 2001). This would be consistent with other studies looking at general anger, which have shown that women tend to experience anger as frequently as men (Kassinove and Sukhodolsky, 1995) The same applies to studies looking at anger expression which have failed to distinguish between the two groups (Thomas, 1989; Campbell, 1997). Although the frequency of both anger and aggression is very similar the reasons and the manner in which it is expressed is not (Kring, 2000). For instance several studies have found that women reported more anger than men following condescending remarks and that men are more likely to get into physical fights, damage property and verbally assault people than women (Kring, 2000). The greater involvement of men in accidents is in accord with previous studies (for example, Al-Balbiss, 2003; Zuckerman, 2008). Men are more impulsive than women (Zuckerman, 2008), impulsivity being the main personality predictor of accidents among men in this study Men tend to take risks more than women (Bell et al., 2000). Previous studies show that men are less conscientious than women (Rubinstein, 2005, 2007; Rubinstein and Strul, 2007), a trait which might be considered as cautiousness and the opposite of impulsivity.

2.6.5 Age and accident proneness

Age has been found to have direct influence on accident proneness among young drivers. Age was suggested to be predictive of accident involvement or accident propensity of young people, especially males. Close parental supervision and gradual expansion of driving rights are protective factors against accident involvement (Hartos et al., 2000). Young drivers tend to drive in more risky and aggressive ways when they are around other male peers, perhaps as a way to demonstrate their manhood, fearlessness and competence (Jonah, 1986).

According to Nell (2002) young males in all species operate in ways to attract females. They act fearlessly to demonstrate their ability to offer protection and compete with other males to gain access to mates. Driving may be one of the few socially sanctioned ways to demonstrate masculinity and aggression in contemporary societies. This may partially explain the higher fatal accident rates when young males drive with male peers as companions (Chen et al., 2000). The social context may also promote this evolutionarily based behavior. Movies and the mass media glamorize fast cars and dangerous driving maneuvers and associate them with masculinity, as in most contemporary action films (Shope, 2006; Arnett, 2002). Bruckner et al. (2011) noted the linear relationship among educational achievement, increased money, vehicle ownership, and accident proneness.

Individuals differ in their propensity toward aggression and young males, in particular, have been noted for their high level of aggression. The same seem to apply to aggressive drivers who are typically young and male (Marsch and Collett, 1986; Lajunen, Parker and Stradling, 1998). In the study by Marsch and Collett (1986) 25 % of the young drivers

aged 17 – 25 would chase another driver if they had been offended. In a study by Krahe and Fenske (2002) another dimension was added namely macho personality. The results showed that young macho men assigned greater importance to speed and sportiness of a car and reported significantly more driving aggression than young non-macho men. The negative association between age and accidents is in accord with many previous studies (for example, Lourens et al., 1999; Zuckerman, 2008). The relative low relation found in our study is a result of the fact that most previous studies investigated much younger drivers (mainly adolescents).

A study by Schlag (1994) found highly significant differences between people under the age of 70 and those over 70 (N=110) on a driving test and in testing using a precursor version of the ATAVT (TAVTMB: Biehl, 1996). Older people were slower to merge on motorway access slip roads, chose a tighter turning radius when turning into a minor road, and in general tried harder to drive in the right-hand lane. They ignored priority rules and red lights significantly more often. Older people more frequently ignored other drivers who had priority, and they crossed a level crossing without barriers without reducing their speed.

2.6.6 Education and accidents proneness

Barribeau (2012) reported that overqualified recent immigrants are three times more likely to be injured on the job than their local, less-educated peers. Looking at 63,462 responses to the 2003 and 2005 Canadian Community Health Surveys, the researchers found that both new immigrants and those who were overqualified for their job were more likely to get injured and when you combine both factors, it's particularly

dangerous combination. By adjusting for other variables, this increase in danger eventually lowered to a threefold more likely chance of being hurt. Sahaand (2014) carried out a study in stone quarries and included 147 children and adolescent workers (81 males and 66 females). They found that Age, nature of work, work hours per day, musculoskeletal complaint and education showed significant effects on workplace injuries proneness.

Pless, Verreault, and Tenina (1989) considered cases of 400 uninjured children seen in the same hospitals for non-traumatic reasons. After adjustment for age, gender and socioeconomic area of residence, logistic regression analyses showed higher risks of injury to be related to fewer years of parents' education, a history of accident to a family member, an environment judged as unsafe, and poor parental supervision. Absence of physical health problems, fewer family preventive behaviours and reported lack of cautiousness were also related to a higher risk, whereas neither aggressively nor behavioural disturbance, whether internalizing or externalizing, showed any such relation.

2.6.7 Personality Traits and Risky Driving Behaviours

Krahe and Fenske (2002) focused on a specific personality trait and risky driving behaviour; the researchers studied the relationship between “macho personality” and aggressive driving. Krahe and Fenske (2002) surveyed 154 men who completed two questionnaires (the Aggressive Driving Scale, and a Violence and Danger Scale) about their personal background and details about the cars they owned. Their findings support

the notion that “individual characteristics of the driver, such as macho personality and age, can predict risky driving behaviour.

Similar to the macho personality just described, another personality trait having a self-concept component is narcissism. Schreer (2002) examined the relationship between this trait and aggressive driving behaviour and found that inflated self-esteem predicted aggressive driving behaviour better than low self-esteem. Furthermore, individuals who scored higher on the Exhibitionism component of the NPI reported higher levels of risky driving behaviour, while Entitlement predicted such behaviour for males only.

Krahé (2005) studied another personality dimension that has a self-concept component, namely, sex role orientation. Specifically, this researcher investigated the relationship between sex role orientation, dispositional aggressiveness, age, and annual mileage using a sample of 256 female drivers. Krahé (2005) found that aggressive behaviour among women decreased as a function of age, but increased as function of annual mileage. Additionally, dispositional aggressiveness was a significant predictor of driving aggression. Specifically, it is the physical aggression component of dispositional aggressiveness that links trait aggressiveness to aggressive driving. As for the effect of sex role orientation on aggressive driving, Krahé (2005) did not show a link between masculinity and driving aggression, but there was evidence in support of a buffering effect of femininity on driving aggression. Finally, contrary to Lajunen and Parker (2001), this study showed a positive correlation between annual mileage and driving aggression. Ellison-Potter, Bell and Deffenbacher (2001) designed one of a few studies using a simulation to study aggressive driving. These researchers examined the effects of traits, driving anger, aggressive stimuli, and anonymity on aggressive driving behaviour

in a simulated driving task. Using a computer-based driving simulation, these researchers found that situational variables such as anonymity and aggressive stimuli were better predictors of aggressive driving than dispositional variables such as trait anger (for example, a predisposition to experience more frequent and intense state anger across a variety of driving situations).

Miles and Johnson (2003) studied the relationship between a wide range of personality dimensions and aggressive driving. Specifically, they investigated the relationship between personality, attitudes, beliefs, and aggressive driving. Specifically, these researchers attempted to identify personality characteristics, attitudes, and belief of people who drive aggressively. Drivers belonging to two groups were surveyed: a group of drivers with multiple traffic citations and a control group of undergraduate psychology students at a large south-eastern university a total of 48 participants out of the former group while 93 participants were included in the latter. Results showed that the two groups differed significantly in terms of driving behaviours, attitudes and belief, and type-A behaviour pattern.

There were no significant differences, however, in the personality characteristics of conscientiousness, agreeableness, and neuroticism. Dahlen and associates conducted two studies that combined several personality dimensions in the study of aggressive driving. Dahlen and White (2006) studied the utility of combining trait driving anger (i.e., the tendency to become angry when encountering frustration and provocation on the road), sensation seeking, and the Big Five personality factors in predicting driving anger expression, and frequency of aggressive and risky driving behaviour. In general, Dahlen and White (2006) found that openness, emotional stability, agreeableness, trait driving

anger, and sensation seeking predicted driving behaviour and outcomes independent of gender, age, and miles/week. More specifically, aggressive driving was predicted by lower scores in emotional stability (for example, higher scores in neuroticism), and increased DAS and scores. Dahlen, Martin, Ragan, and Kuhlman (2005) investigated the combined effect of trait driving anger, sensation seeking, impulsiveness, and boredom proneness on driving behaviour.

These researchers surveyed 224 undergraduate students, found a moderate relationship between aggressive driving and both impulsiveness and external boredom (for example, 11 boredom due to the lack of external stimulation). It also found that sensation seeking predicted aggressive driving. Similar to Dahlen and, Harris and Houston (2010) studied the combined effect of several personality dimensions on aggressive driving, but they also added situational variables to their analyses. These researchers investigated personality variables that included hostility, sensation seeking, and competitiveness. Results showed a positive correlation between horn honking and hostility, boredom susceptibility, competitiveness, and being male, with only hostility and boredom susceptibility remaining as significant predictors in the multiple regression analysis. As for tailgating, the results showed a positive correlation with hostility, thrill and adventure seeking, boredom susceptibility, and competitiveness, with only the first three remaining significant predictors in the multiple regression analysis.

Finally, Harris and Houston (2010) found a significant main effect for time pressure on horn honking with a marginal interaction effect (for example, although both men and women admitted to more honking when pressed for time, this situation was

more pronounced among women). Similarly, for tailgating in both males and females reported that they were more likely to tailgate when pressed for time.

Schwebel, Severson, Ball, and Rizzo (2006) studied both the independent and combined effects of three personality traits (namely, sensation-seeking, conscientiousness, and anger/hostility) on risky driving behaviour. These researchers collected data from 73 (41% male, 55% female, and 4% unknown sex, and ranging in age from 21 to 51) college students from introductory psychology courses at the University of Alabama at Birmingham. Schwebel et al. (2006) found that sensation-seeking, conscientiousness, and angry/hostile behaviour patterns each predicted risky driving on self-reports, and, like Dahlen et al. (2005), that these personality traits contribute incrementally to explain risky driving. However, no personality trait predicted risky driving in the simulator.

Arthur and Day (2009), investigate whether reported risky driving behaviors measured by driver violations, error and lapse (items of the Driver Behavior Questionnaire (DBQ) will differ across the Big Five personality traits (openness, conscientiousness, extraversion, agreeableness and neuroticism). They found that Drivers who reported low driver violation scored higher on conscientiousness and agreeableness. Drivers who reported high violations were more extraverted. Conscientious drivers also reported low driver error and lapse. Drivers high on driver lapse scored higher on neuroticism. There was no difference in DBQ items across openness. The study concluded that there are different elements of risky driving which differ across some of the Big Five personality traits.

On the five personality factors the study showed that low emotional stability generally predicts aggressive behaviour as well as its factors except negativism. Numerous studies have investigated the relation between emotional stability and driving style. Taubman - Ben Ari and Yehiel (2011) found that people with low scores on emotional stability practice an anxious driving style. Also, Dahlen, et al. (2011) demonstrated that emotional stability relates negatively with aggressive driving, road accidents and traffic violation while Dahlen and White (2006) show that there is a negative relation between emotional stability and anger behind the wheel. Jovanovic et.al (2010) highlights that people with high scores on the emotional stability factor show a high level of physical and verbal aggression in traffic.

Extraversion, which means the pleasure of interacting with others, the tendency to be assertive, sociable, energetic, outward (John and Srivastava, 1999) was studied in relation to aggressive driving behavior, some studies finding a positive relation between extraversion and reckless driving (Renner and Ander, 2000). The study by Benfield, Szleko and Bell (2006) shows that there is a positive correlation only between extraversion and physical aggression in traffic and other traffic subscales of aggression such as verbal aggression, adaptive and constructive behavior or traffic challenges, do not correlate significantly with extraversion . Martin and Boosma (1989) have shown that people with high scores on the scale of extraversion under the influence of alcohol show a high level of aggressiveness while driving. Dahlen and White (2006) showed that extraversion predicts reckless driving and traffic accidents, the high level of extraversion being one of the causes of road accidents.

People with high scores on the openness factor tend to be characterized by aesthetic appreciation, values, idea acceptance, self-actualization, personal growth and development (McCrae and Costa, 2006). Unlike other factors of the Big Five model, few studies have found significant relation between openness and aggressive driving behaviour (Jovanovic et al 2010). Taubman - Ben-Ari and Yehiel (2011) studied the openness factor in the context of driving styles, finding a positive relation between openness and careful driving style while between styles characterized by aggressive, anxious and hostile behaviour, there was no significant association with openness.

Among the few studies that have found the openness factor associated with aggressive driving behavior is that of Dahlen and White (2006), the authors showing a negative link between openness and reckless driving, individuals with high scores on openness factor being less prone to engage in risky traffic than those with a low score.

People with a high score on agreeableness practice careful driving style, and those with a low score drive in a angry, reckless, anxious and desolate way (Taubman - Ben - Ari and Yehiel, 2011). Also, people with a high score on agreeableness are characterized by adaptive behaviours in traffic while people with low scores show a high level of verbal aggressiveness when driving (Benfield et.al, 2006). Dahlen& White (2006) found that people with high levels of agreeableness do not practice reckless driving, and have a low level of aggressive behaviour in traffic. In addition Dahlen et.al (2011) negative relationship have been found between agreeableness and violation of traffic rules, people with low scores on agreeableness factor, often violating traffic rules. Also, a negative association was found by Jovanovicet.al (2010) between agreeableness and manifested

anger while driving, traffic participants with low scores on agreeableness behaved more hostile and more furious than those high on agreeableness.

Arthur and Graziano Jr. (1996) have demonstrated the existence of a negative relation between conscientiousness and involvement in accidents. Thus, those with a high score on this factor, being characterized by organization and self-discipline, are rarely involved in traffic accidents than those with low conscientiousness scores. Jovanovic et.al (2010) show that physical aggression and verbal aggression manifested while driving relate negatively with conscientiousness, those with high scores on this factor manifesting a reduced physical and verbal aggressive behavior when driving, than those with small scores. Moreover, Benfield et.al (2006) show that a high score on this trait relates positively with constructive and adaptive behaviours in traffic and relates negatively with verbal aggression behind the wheel. It should be noted that even though the foregoing review of the literature exemplifies several ways of defining “aggressive driving” (some focusing on emotional while others on cognitive aspects), the present research adopts Harris and Houston’s (2003) approach of measuring aggressive driving in a way that is void of any reference to emotional or motivational states, and in which consideration is given only to the frequency of specific driving behaviours. Thus, in light of this previous work on aggressive driving, and in attempt to furthering our understanding of aggressive driving behaviour,

Personality traits can be defined as dimensions of individual differences in the tendency to show consistent patterns of thoughts, feelings and behaviour (McCrae and Costa, 1995; Tellegen 1991). Personality traits are thought to influence behaviour. Cattell (1950) has stated one of the most deterministic views pertaining to the influence of personality traits

on behaviour. Although traits have low predictive value of single situations, Epstein (1977) has shown that traits show high correspondence with aggregate measures of behavior. The role of personality traits in traffic accidents has been central in explanations emphasizing accident proneness (Farmer and Chambers, 1939; Tillman and Hobbs 1949).

The notion that *one* general personality trait is the cause of drivers' accident involvement has, however, been rejected. Still, the influence of personality on driving behaviour and accident involvement is not totally abandoned. A range of studies have found personality traits to be weak, but consistently associated with accident involvement in traffic. There is, however, reason to believe that the role of personality traits pertaining to accident involvement in traffic may be underestimated. As implied by Everitt (1977), general measures such as personality traits are assumed to be weak predictors of a single event measure such as a traffic accident. This difficulty is further augmented due to the fact that traffic accidents are relatively rare, and influenced by numerous other factors than the driver's behaviour in traffic (Fridstrøm, Ifver, Ingebrigtsen, Kulmala and Thomsen, 1995).

Sensation seeking can be said to be the personality trait most frequently studied in relation to driving behaviour and traffic accident involvement. Sensation seeking is defined as a need to experience novelty, excitement, and dangers (Zuckerman, 1979). Several researchers have suggested that risky driving is motivated on the basis of the sensation-seeking thrill this causes for some individuals (Arnett, 1990, 1991; Jonah, 1997).

The motivational influence of sensation seeking on risky driving behaviour is further supported by findings demonstrating that sensation seeking explains a large part of the variation in the propensity to commit driving violations, but accounts for very little of the variance in the tendency to commit driving errors (Rimmö and Åberg, 1999).

A range of other personality factors are also related to risky driving and crash involvement. The most prominent ones are mild social deviance, hostility, Zuckerman (1979) has divided the trait sensation seeking into four dimensions: Thrill and adventure seeking (seeking dangers), excitement seeking (seeking unusual sensations), inhibition (mild social deviance), and Boredom Susceptibility (intolerance for repetitive experiences).

Aggression, impulsiveness, emotional liability, locus of control, and antisocial motivation (Arthur, Barrett and Alexander, 1991; Hilakivi, Veilahti, Asplung, Sinivuo, Laitinen and Koskenvuo, 1987; One may, however, ask oneself what the point of studying the role of personality variables is since it is unrealistic to be able to change a driver's personality. Would it not be more meaningful to study only motivational beliefs that are more open to change, such as risk-taking attitudes? The reason for focusing on personality traits in the present thesis is because traits are thought to influence the individual's perception and appraisal of the environment (McCrae and Costa, 1995).

2.6.8 Alcohol Use and Risk Driving Behaviour

Scott-Parker, Watson, King and Hyde (2014) explore the: (1) self-reported compliance of drivers with road rules regarding substance-impaired driving and other risky driving behaviors (e.g., speeding, driving while tired), one year after progression from a Learner to a Provisional (intermediate) licence; and (2) interrelationships between substance-impaired driving and other risky driving behaviors (e.g., crashes, offences, and Police avoidance).

A relatively small proportion of participants reported driving after taking drugs (6.3% of males, 1.3% of females) and drinking alcohol (18.5% of males, 11.8% of females). In comparison, a considerable proportion of participants reported at least occasionally exceeding speed limits (86.7% of novices), and risky behaviours like driving when tired (83.6% of novices). Substance-impaired driving was associated with avoiding Police, speeding, risky driving intentions, and self-reported crashes and offences. Forty-three percent of respondents who drove after taking drugs also reported alcohol-impaired driving. Substance-impaired driving is problematic for young, inexperienced drivers; other risky driving behaviours such as speeding, carrying passengers, and driving tired are also of concern. Young drivers who crashed whilst under the influence of alcohol in the United States between 2005 and 2009 were more likely to be males who were speeding, not wearing a seatbelt, and carrying passengers on a weekend night (Williams et al., 2011). Substance-impairment may reduce wearing of seatbelts and increase the number of passengers carried; young drivers occasionally are found to carry more passengers within the cabin of passenger vehicles than there are seats (and therefore seatbelts) (e.g., see Calligeros, 2009). Young drivers also drive at times which are in

conflict with circadian rhythms and which may also involve alcohol and carrying peers who may be a negative influence upon their behaviour (Papadakaki et al., 2008). Further, regular mobile phone users report frequent speeding, crashes and driving violations (Schlehofer et al., 2010).

2.6.8a Personality Traits and Accident Proneness

The driving literature have revealed that motivations like competitiveness, sense of power and control, or just pursuing sensual pleasure may impinge on the way one drives and may influence a person's being prone to accidents (Evans, 1991). Also, vehicles are often used as an outlet for independence, emotional expression, rebelliousness, and to satisfy peer-acceptance needs of young drivers (Jessor, 1987). Based on these drivers high on neuroticism are more likely to drive dangerously and be involved in accident situations frequently. Also Aworeni et al., (2011) concluded that there is relationship between human characteristics, vehicular characteristics, roadway characteristics, environmental characteristics.

Liao et al. (2001) have found that fire-fighters who were introverts were less likely to call for assistance, and as fire-fighting requires a high degree of teamwork, it might be that the less integrated and sociable members of the team exposed themselves to greater personal risks. Extroversion is associated with being impulsive and this has been found to be a feature in people who have car accidents and accidents at work (Furnham and Heaven, 1999). Other equally important variables were included in the first factor: driving during bad weather conditions, driving while using mobile phone and overtaking in dangerous situations. Secondly, the factor "distraction" is associated to the distractive

behavior. A study conducted by Deffenbacher et al. (2003) led to the conclusion that lapses of concentration are associated with risky driving behavior. Finally, a third dimension -labeled “driving errors of omission”- is associated to little or no signaling light use. Social, cognitive and personality variables influence the driving process and, consequently, the absence or existence of accidents. In line with previous studies (Arthur and Graziano, 1996; Blanchard, Barton & Malta, 2000; Dahlen and White, 2006; Jonah, 1997; Lajunen and Parker, 2001; Schwebel et al., 2006) driver’s personality is a good predictor of dangerous driving behaviour Iversen, and Rundmo 2002, Furnham and Heaven 1994. This corroborates the results from previous studies that show that personality characteristics is significantly relating to driving. Fergusson, Swain-Campbell, and Horwood (2003) who examined the prevalence of risky driving behavior among young people, the characteristics of those who engage in risky behaviours driving behaviour and the association between risky driving and accident risk. More than 90% of drivers engaged in some form of risky driving behaviour.

Those most likely to engage in frequent risky driving behaviours were: males who exhibited alcohol or cannabis abuse use. There was a strong association between the extent of risky driving behaviour and traffic accident risk. This result is similar to that of Iversen,; Rundmo,-Torbjorn (2000) who found that drivers involved in risk taking-behaviour experienced near-accidents and crashes leading to both injuries and material damage more often than other drivers. Similar results were found by Buss et al., 1993; Huebner, and Porter-Marshall 2006, and Judges (1993). In the same vein, Begg and Langley (2004) found that personality trait of low constraint (for example, low scores for control, harm avoidance, and traditionalism), aggressive behaviour, and cannabis

dependence predicted risky driving behaviour. These are characteristics to be borne in mind when developing programmes for young drivers that aim to deter the development of persistent risky driving behaviour. Schell and colleagues explored the role of attitudes, behavior and personality variables in driving under influence of alcohol (DUI) (Schell et al., 2006).

They found a near zero correlation between DUI and Impulsivity and Hostility when they controlled for socially desirable responding bias, and no relation at all between Sensation seeking and DUI when this relationship was adjusted for behavior factors such as drinking frequency and high risk driving style. Ulleberg and Rundmo (2003) also found that the effect of person

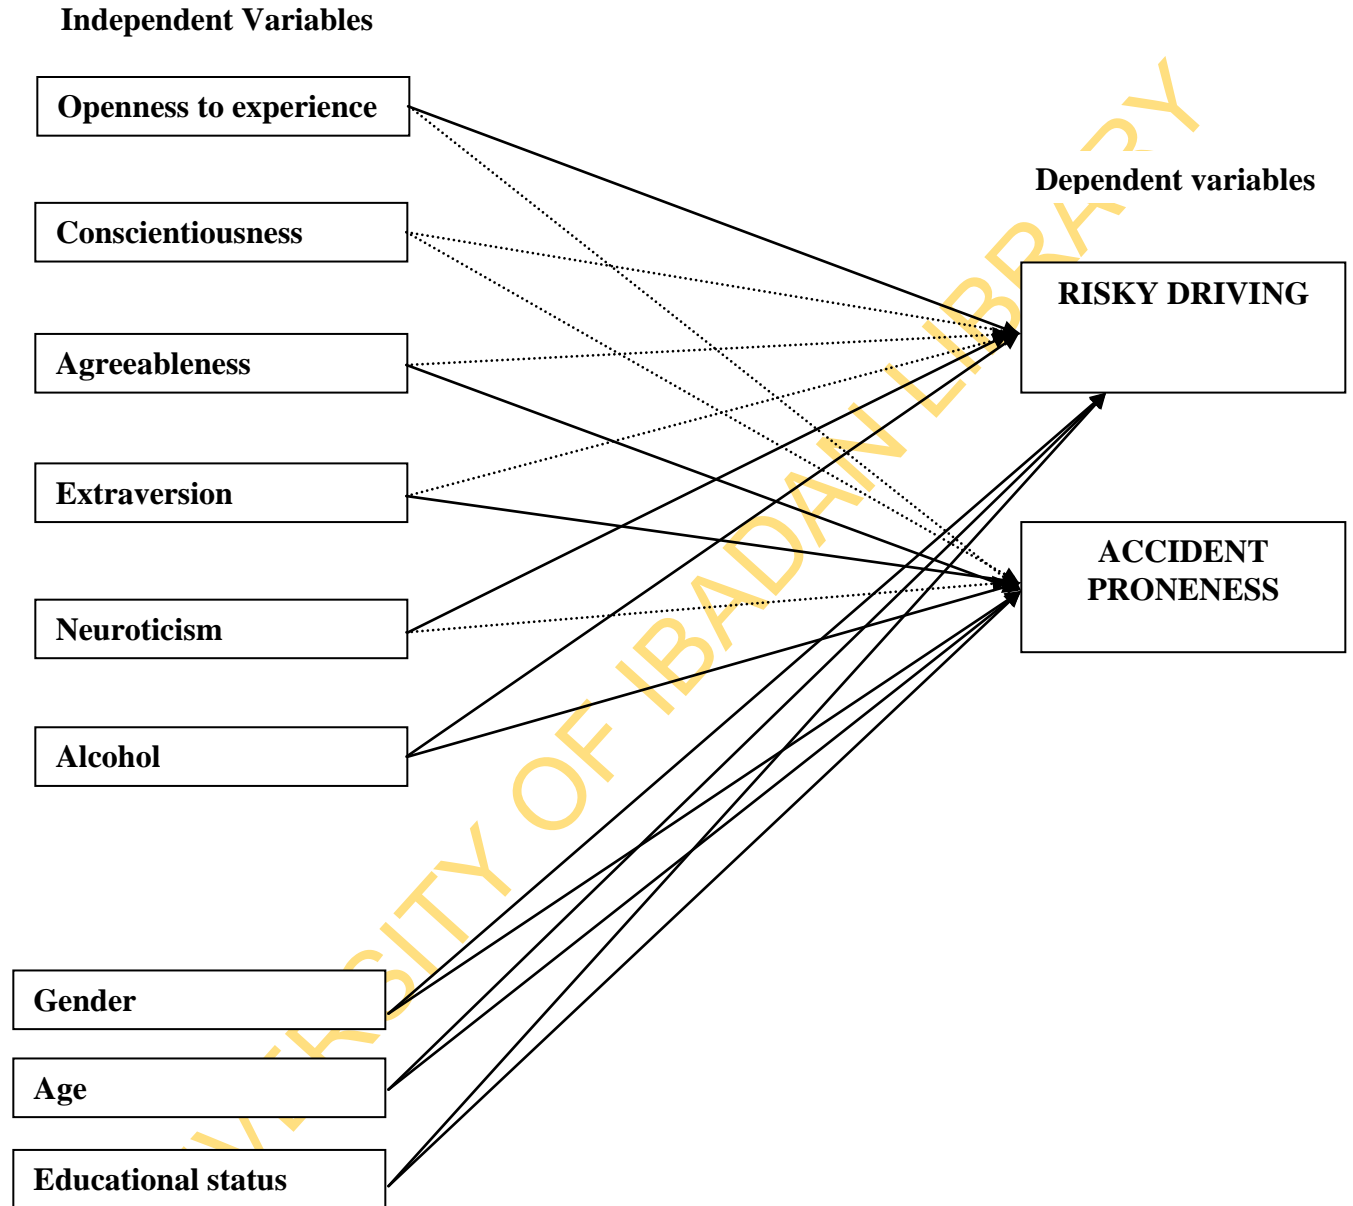

2.6.9 Alcohol use and accident proneness

The role of alcohol according to Cameron (1982) indicates that a large proportion of alcohol and non -alcohol involved crashes involve drivers under the age of twenty-five. This is the case even when differential exposure to traffic crashes has been controlled for. In a recent review, Mayhew, Donelson, Bierness and Simpson (1986) concluded that young drivers who drive after drinking had a greater risk of crash involvement than older drinking drivers, although the young drivers were less likely to drink and drive. Mayhew et al make the suggestion that the higher crash risk of young drivers may be due to inexperience with drinking and/or driving. In an interesting study, Donovan and Marlatt (1982) attempted to identify through the use of cluster analysis personality sub-types of drivers who drive while under the influence of alcohol.

Rubinstein (2013) investigated the relation between the NEO-PI, ImpSS, and involvement in car accidents among 1,500 participants, who comprises a representative sample of the adult Jewish population in Israel during 2009-2011. The results show car accident proneness: Drivers who had been involved in accidents prior to the study were involved in accidents during the study more than those who had not been involved in accidents prior to the study. However, not a single pedestrian, who had perceived himself or herself responsible for accidents prior to the study was involved in accidents during the study, but no significant accident rate differences have been found between drivers who had perceived themselves responsible and irresponsible in causing pre-study accidents. In line with previous studies, men were significantly more involved than women in car accidents and a negative association was found between age and involvement in car accidents was the main personality predictor of accident involvement among male drivers, while the authoritarianism factor of the openness to experience scale served as an additional predictor among female drivers

2.6.9a. Conceptual Framework

2.6.9b. Psycho-social model of accident proneness and risky driving behaviour

Source: Researcher (2014)

Prediction of accident occurrence and assessment of risky driving behaviour is based on the premise that accidents in general are not due to chance alone and the study focuses on the role of dispositional and risk factors. This study proposed a direct link personality's trait as a dispositional factor responsible for risky driving behaviour and accident proneness among the present sample. In addition the study also holds alcohol use as factors contributing to the risky driving and accident proneness. In order to control for the influence of socialization factor in the study age, gender and education were included in the model towards explaining the psycho-social model risky driving and accident proneness models.

The path proposed is that high concentration of alcohol in the blood stream is that the victims' reactions are slower with contribution of low conscientiousness, high neuroticism and extraversion traits to risky driving and crash involvement. All these factors are assumed to represent the basic structure behind all personality traits. These models will be tested not neglecting the contribution younger age, being a male and low educational attainment in risky driving behavior and accident proneness. This study also expects a positive relationship between the risky driving behaviour and accident proneness among the present sample. The conceptual model path is broken into the hypotheses in section 2.6.

2.7 HYPOTHESES

1. Male drivers will be more significantly prone to risky driving behaviour than female drivers.
2. Male drivers will be more significantly accident prone than female drivers
3. Educational qualification will significantly influence the level of risky driving behaviour among injured drivers.
4. Education level will significantly influence accident proneness among injured drivers.
5. Younger drivers will significantly engage in high level of risky driving behaviour than older drivers among injured drivers.
6. Younger drivers will significantly be more accident prone than older drivers among injured drivers.
7. Personality factors and alcohol use will independently and jointly predict risky driving behaviour.
8. Personality factors and alcohol use will independently and jointly predict accident proneness.
9. All the Psychological and social variables will significantly independently and jointly predict risky driving behaviour among injured drivers
10. Psychological and social variables will significantly independently and jointly predict accident proneness among injured drivers.

2.8 OPERATIONAL DEFINITION OF TERMS

Risky driving behaviour: -This refers to drivers' driving behaviour that puts the occupant of the vehicle and the vehicle at the risk of accidents. Such behaviour include over speeding, making phone calls while driving. They can range from being mild to dangerous driving .This was measured in this study using a 10-item driving behaviour scale developed by the researcher. The mean score is 23.01. High scores above the mean score on the scale indicate higher aggressive driving behaviour, while low score below the mean on the scale indicates lower Aggressive driving behaviour.

Accident proneness: Certain numbers of accidents over a period of time. These include individual who experience accidents due to more than mere bad luck. This behaviour was measured in this study using a 10-item adapted from Sicco Van As (2006). The mean score is 27.21. High scores above the mean score on the scale indicate higher accident proneness, while low score below the mean on the scale indicates lower accident proneness.

Alcohol use: Is a chemical substance capable of altering the physical, biological, or psychological functions of the body. Alcohol use could be used in form of local cocktails like; Hot (Ogogoro), opa-eyin, Ogun Jedi. Drug use was captured using Alcohol disorder identifications tests (AUDIT) developed by Saunders, Aasland,Babor, de le Fuente, and Grant (2006). High score on the scale indicates frequent drug use behaviour, while low score on the scale indicates lower drug use behaviour.

Personality : personality is the individual characteristics of a person that which for us means exactly the same as developing *personality traits* was measured in this study using

the "Big Five" factors of personality which is a five broad domains or dimensions of personality described below:

Extroversion traits: refers to trait characterized by a keen interest in other people and external events, and venturing forth with confidence into the unknown. This was measured using the 16 – item big five personality scale developed by Buchanam, Coldberg and Johnson (1999)

Neuroticism trait: is the other trait that is "a dimension of personality defined by stability and low anxiety at one end as opposed to instability and high anxiety at the other end". This was measured using the 7 – item big five personality scale developed by Buchanam, Coldberg and Johnson (1999)

Openness to experience trait: refers to how willing people are to make adjustments in notions and activities in accordance with new ideas or situations. This was measured using the 7 – item big five personality scale developed by Buchanam, Coldberg and Johnson (1999)

Agreeableness traits: refers to how compatible people are with other people, or basically how able they are to get along with others. This was measured using the 7 – item big five personality scale developed by Buchanam, Coldberg and Johnson (1999)

Conscientiousness traits: refers to how much a person is organized and considers others when making decisions. This was measured using the 7 – item big five personality scale developed by Buchanam, Coldberg and Johnson (1999)

Educational Level – refers to the level of educational qualification of patients. This is grouped into low and higher. Patients that possess OND /NCE certificate and above are regarded as higher educational status while patients with SSCE and below are regarded as lower educational status.

Age: This refers to the number of years a person has lived. This was captured by asking for the age of the patients as at last birthday of the patients. In his study age was categorized into two levels (young and old)

Gender: refers to the biological differences between men and women. This was captured by asking whether the patient is a male or female.

UNIVERSITY OF IBADAN LIBRARY

CHAPTER THREE

METHOD

3.1 RESEARCH DESIGN

The study adopted cross sectional survey design because the respondents were from different towns and cities, they were studied simultaneously and their behaviour were compared. The independent variables are personality traits and alcohol use while the dependent variables are risky driving behaviour and accident proneness. The socio-demographic variables are age, marital status, education and Socio-economic status.

3.2 RESEARCH SETTING

The setting is Ladoke Akintola University of Technology Teaching Hospital .This tertiary hospital has about 500 beds and 3000 workers. Ladoke Akintola University of Teaching Hospital's workforce includes Consultant Family Physicians, Nurses, Physiotherapists, Optometrists, General Surgeons, and Orthopedic surgeons. Services provided at this hospital include: outpatient, admissions, laboratory, minor and major surgeries, ultrasound scanning, pharmaceutical service and ambulance services. The location of the study was the Accident and Emergency Unit, Orthopedics Wards, Physiotherapy Unit, and Clinics of the Hospital. The hospital provides diagnostic and treatment services for people in Osun state, Oyo state and neighbouring states in south west zone of Nigeria. The accident and emergency department comprises of Consultants, Resident doctors, Nurses while the Physiotherapy unit also has similar compositions, Apart from this, the hospital is centrally located in the state capital which is easily accessible by all motorist and the general public.

3.3 SAMPLING PROCEDURE

The study was conducted in a Teaching Hospital at Osogbo, the Osun state capital, from this hospital a total of one hundred and twenty respondents were consecutively selected, Respondents were sampled using consecutive sampling from the admitted or hospitalized patients.

Consecutive sampling is very similar to convenience sampling except that it seeks to include ALL accessible subjects as part of the sample. This sampling technique can be considered as the best of all non-probability/non-random samples because it includes all subjects that are available that makes the sample a better representation of the entire population. Thus, patients willing to participate in the study were interviewed and between five to ten patients were sampled daily. The study took place between 1st July and 31st August, 2012. Consecutively sampling does not require sample size calculations since it is a non-probabilistic sampling procedure. Non-probability sample is not a product of a randomized selection processes. Subjects in a non-probability sample are usually selected on the basis of their accessibility or by the purposive personal judgment of the researcher.

Consecutively is used when; demonstrating that a particular trait exists in the population, the researcher aims to do a qualitative, pilot or exploratory study, randomization is impossible like when the population is almost limitless etc (Explorable.com, 2015)

3.4 INCLUSION AND EXCLUSION CRITERIA

Inclusion criteria: the respondents that were eligible in the study fell into the following categories:

- (a). A driver that was involved in an accident
- (b). A driver that was licensed or not
- (c). A driver receiving medical care either in or outpatient basis.

Exclusion criteria: Patients who were excluded from the study include patients who were in the wards diagnosed with problems other than those resulting from car or vehicular accidents. Also excluded were accidents victims who were non- drivers or accidents victims not driving during the period.

3.5 RESEARCH INSTRUMENT

The instrument that was used in this study is questionnaire for both independent and dependent variables. Three existing scales were used while one scale was developed by the researcher. The questionnaire were divided into five sections with each section measuring different aspects.

Section A: Social demographic variable tapped information such as age, gender, marital status, educational level, socio-economic status and, religion. Age was measured using the real age given by the drivers. Gender was coded as 1= male and 2=female. Marital status was coded as married =1 and single = 2; Education level was coded as all drivers with SSCE and below were regarded as having low education and those with OND and above were regarded as having higher level education. Religion was coded as Christianity = 1, and Islam = 2.

SECTION B : Risky Driving Behaviour Scale (RDBS)

Scale Development and Pilot Study: The risky driving behaviour scale was developed by the researcher. The researcher first tried to identify various activities of the people regarding risky driving behaviour of drivers. The researcher then interviewed 30 people to give reasons for motor accidents. The items included what they experience driving after drinking alcohol, breaking speed limits, driving during bad weather, overtaking in dangerous situations, destructive behaviour and little or no signal light use in the past. A pilot study was embarked on to generate items for the construction of questionnaire to tap people's perception of risky driving behaviours among key officers of drivers. This was done through some open ended questionnaire which gives opportunity for respondent to express their thought about the factors influencing their decision in driving in risky manner. The questionnaire administration was done directly and this procedure resulted in a pool of 15 items. A pilot study of the 15 items generated using a sample of thirty drivers from major motor parks (chairmen, secretaries and other key officers) whose age range from 20 to 55 years.

ITEMS GENERATED

I drive when I am angry

I lose my temper when driving

I consider the actions of other drivers to be inappropriate or stupid

When I get stuck in a traffic Jam I get irritated

I feel that passive drivers should learn how to drive or stay home

I flash my headlights when I am annoyed by another driver

I make rude gestures (For example giving "the finger", yelling curse words) toward drivers who annoy me

I verbally insult drivers who annoy me

I deliberately use my car/truck to block drivers who tailgate me

I would tailgate a driver who annoys me
I will illegally pass a car/truck that is going too slowly
I will drive if I am only mildly intoxicated or buzzed
I will cross double yellow lines to see if I can pass a slow moving car
I will drive when I am drunk
I consider myself to be a risk taker

An item-total correlation analysis was carried out and only items that met the coefficient of 0.42 and above were included for use in this study. Content analysis using with total item correlations was then carried out to extract the significant items and discard items which did not have baseline item loading of 0.42.

UNIVERSITY OF IBADAN LIBRARY

Cronbach's Alpha	N of Items
.82	10

Item-Total Statistics

	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item-Total Correlation	Cronbac h's Alpha if Item Deleted
I make rude gestures (For example giving “the finger”, yelling curse words) toward drivers who annoy me	16.58	62.347	.650	.789
I verbally insult drivers who annoy me	17.19	69.201	.545	.803
I deliberately use my car/truck to block drivers who tailgate me	16.73	70.849	.528	.805
I would tailgate a driver who annoys me	16.82	68.455	.604	.798
I will illegally pass a car/truck that is going too slowly	16.63	66.458	.531	.804
I will drive if I am only mildly intoxicated or buzzed	16.37	71.774	.430	.814
I will cross double yellow lines to see if I can pass a slow moving car	16.36	67.088	.433	.818
I will drive when I am drunk	17.30	66.518	.633	.793
I consider myself to be a risk taker	17.11	66.868	.592	.797
I make rude gestures (For example giving “the finger”, yelling curse words) toward drivers who annoy me	17.76	78.712	.345	.837

The reliability was derived from the result of the analysis which revealed that the cronbach's alpha for the initial analysis was $\alpha = 0.72$, after which 5 items were deleted from the total number of 15 items for weak performance using the .3 criterion set for corrected item total The cronbach's alpha rose to 0.82. The scale also reported a split half reliability of .83, spearman brown prophecy co-efficient. Thus the remaining 10 items was used in this study.

RISKY DRIVING BEHAVIOUR

This section measured risky driving behaviour of drivers; the participants answered structured questions that were developed by the researcher; items were selected from interview guide and an in-depth interview guide schedule. The questionnaire were rated on a 5 point frequency scale ranging from 0 (never) to 4 (frequency). Reliability test was done on the items and it has Cronbach's Alpha of .87 the reliability for the main study was 0.81 cronbach's alpha.

The instrument were used to assess risky driving behaviours and considered the following seven variables: driving after drinking alcohol, breaking speed limits, driving during bad weather, overtaking in dangerous situations, destructive behaviour and little or no signal light use.

Section C: Accident proneness questionnaire is a 10-item scale designed by Sicco Van As (2006), the ten items together has a Cronbach's Alpha = .75 , Four items in the scale measure near accident and drivers' general opinion about their safety, the remaining six items measured mistakes and risk taking behaviour. Before the main study commenced the scale was revalidated and the reliability checked. The reliability of 0.84 Cronbach alphas was recorded. The split- half reliability was 0.88 Spearman- Brown coefficient. The reliability for this study is 0.79 Cronbach's alpha.

Section D: This section consisted of Alcohol Use Disorder Identifications Tests (AUDIT) developed by Saunders, Aasland, Babor, de le Fuente, and Grant (2006) The AUDIT is a 10-item screening instrument developed by a WHO collaborative study conducted in six countries: Australia, Kenya, Bulgaria, Norway, Mexico and the USA. It was designed to screen for a range of drinking problems and in particular for hazardous and harmful

consumption of alcohol. The psychometric properties of the AUDIT have been assessed across a range of populations, including university students, women, psychiatric patients, geriatric population and unemployed people. The final 10 items from the AUDIT were selected from a 15-item interview schedule. The basis of selection was determined both through statistical analysis and face validity.

The questions were selected from four conceptual domains: alcohol consumption (items 1-3), drinking behaviors related to dependence (items 4-6), adverse psychological reactions (items 7-8) and alcohol-related problems (items 9 and 10). A score of eight is associated with harmful or hazardous drinking. As a general guide, a score of 13 or more is likely to indicate alcohol dependence. Overall the AUDIT is a comprehensive brief screening device providing information on hazardous harmful use, abuse and dependence. Authors have reported varying alpha levels for this instrument ranging from ($\alpha = 0.77$ to 0.89) this scale was also revalidated and the reliability checked. The reliability of 0.98 Cronbach alpha was recorded, the split half reliability was 0.93 Spearman Brown coefficient.

Section E: This is the Big Five (BFI) inventory measuring the big five personality factors jointly developed by Buchanan, Goldberg and Johnson (1999). The inventory contains 36 items measuring extroversion, neuroticism, agreeableness, openness to experience and conscientiousness. On the scale, extroversion was measured with items 3, 10, 13, 15, 19, 24, 29, 35, 36, and 37; Neuroticism was assessed with items 1, 2, 6, 9, 25, and 31. Agreeableness was measured with items 7, 8, 16, 21, 27, 32, and 33; openness to experience item was measured with 12, 14, 20 and 22. Conscientiousness items were 4, 5, 11, 17, 18, 23, 25, 30 and 31. The reversed scored items were 1, 6, 8, 9, 10, 12, 18, 20, 22,

26, 31, 37 that is reverse scoring). Cronbach's alpha for each dimension of the inventory are as follows: openness 0.74, conscientiousness 0.84, extroversion 0.88, agreeableness 0.76 and neuroticism 0.83. The scales were scored on a 5 – point Likert-type response format ranging from strongly agree (SA) to strongly disagree (SD) in its scoring . Before the main study commenced the scale was revalidated and the reliability checked. The reliability reported shows that Neuroticism have reliability alpha of 0.79, agreeableness = 0.64 cronbach's alpha, openness to experience = 0.67 cronbach's alpha, conscientiousness = 0.80 and extraversion was 0.78 cronbach's alpha. The reliability reported for the main study shows that Neuroticism have reliability alpha of 0.76, agreeableness = 0.74 cronbach's alpha, openness to experience = 0.87 cronbach's alpha, conscientiousness = 0.82 and extraversion was 0.68 cronbach's alpha.

3.6 PROCEDURE

Ethical clearance to conduct the study was obtained from LAUTECH Teaching Hospital Ethical Ethics Committee. Permission was also obtained from the consultants and matrons' in-charge of the clinics, while a written informed consent was obtained from each selected patient. The first phase of the main study was re-evaluation of the standardized scales that was used for the study. Reliability of the measure needed to be demonstrated by confirming the internal consistency of the constructs (for example, by use of Cronbach's α) and by confirming dimensionality (for example, by using factor analysis).

In the pilot study all 77 items from the original questionnaire were used. Both the current and authors reported validity of the scales were all confirmed and considered to be

good. Items with low total item correlation and low factor loading of 0.3 were deleted from the study.

For the main study the researcher employed the consecutive sampling procedure to sample one hundred and twenty injured drivers. The respondents were selected at accident and emergency unit, orthopedic unit, and physiotherapy unit. The data collection exercise was preceded with advocacy visits to various units' area of the site study; in each unit the staff and heads of the unit received the researcher warmly. The first stage questionnaires were given to drivers at all chosen motor parks. This was done through the executive officers of each park and an allowance of two weeks was given before the retrieval of the questionnaire.

This questionnaire was first translated from English language version into Yoruba version, so that those who were not literate amidst the respondents would have opportunity to participate in the study. The questionnaire was translated to Yoruba the native language to ensure clarity and non-ambiguity as well as to reduce inter-observer variation interpretation during the interview. The study recorded a hundred percent response rate for the study. All the questionnaires were adequately filled and completed.

3.7 STATISTICAL ANALYSIS

The data was coded and analysed using Statistical Package for the Social science (SPSS) version 20 software (IBM, 2012).The socio-demographic characteristics were analysed using frequency count and simple percentage. The item analysis and validity test were carried out using cronbach alpha and factor analysis. Cronbach alpha was used to estimate the reliability of all the scales and factor analysis was used to get a small set of

uncorrelated dimensions from the large set of items generated for newly developed scale. The study utilised the exploratory factor analysis; this is utilised when the researcher do not have a pre-defined idea of the structure or how many dimensions are in a set of variables.

The inferential statistics utilised in this study include t-test for independent samples, Multiple regression, and hierarchal multiple regression analyses to test the ten hypotheses in the study.

Hypotheses 1- 6 were tested using the independent samples t-test, also called the two samples t-test or student's t-test. This was used to determine whether statistically significant differences exist between two unrelated groups looking at their mean scores on the dependent variable.

Hypotheses 7 and 8 were tested using multiple regression analysis. Multiple regression analysis is used when one is interested in predicting a continuous dependent variable from a number of independent variables.

Hypotheses 9 and 10 were tested using Hierarchical multiple regression. This is to establish how each group of socio-demographic characteristics, personality traits and alcohol incrementally contributed in the building successive linear regression models or incrementally contributed to the prediction of the dependent variables.

CHAPTER FOUR

RESULTS

This chapter deals with data analysis and interpretation of result of the study The statistical tests used include multiple regression analysis for testing composite relationship of the independent variables and t-test for independence to ascertain the level of differences between different levels of independent variables on the two dimension of the dependent variable in the study.

4.1 SOCIO DEMOGRAPHIC INFORMATION ON PARTICIPANTS IN THE STUDY

Fig.4.1: Gender proportions of Male and Female participants in the study.

Larger proportions 90% of the respondents are male while 10% are female, this may be because driving is predominantly male business.

Religion

Fig: 4.2: Religion Larger proportions 75% are Christians, 23% are Muslims and 2% are traditionalist

Marital Status

Fig. 4.3; Marital status Majority 64% of the respondents are married while 36% are single

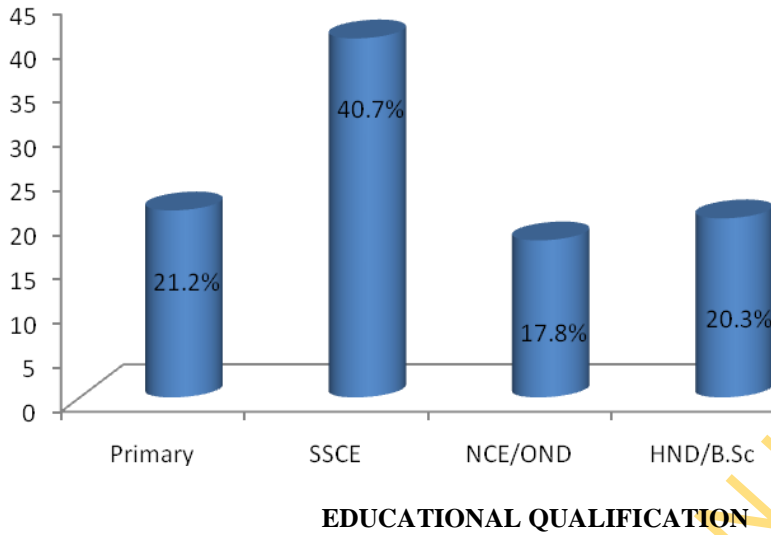

Fig.4.4: Educational Qualification 21.2% of the respondents acquired primary school certificate, larger proportion 40.7% possesses secondary school certificate, 17.8% are NCE/OND holder and 20.3% acquired HND/B.Sc certificate.

Fig 4.5: Training years 68% of the respondents reported that they spent between 1-4 years for training, 21% spent between 5-10 years and 10% reported spending above 10 years.

4.6: 20% of the respondents belong to age bracket between 20- 25 years, the larger proportion of 48% falls between the age group of 26-30 years and 32% are above 31 years of age.

Hypothesis one stated that male drivers will be significantly more prone to risky driving behaviour than female drivers among injured drivers. This hypothesis was analyzed using the t-test for independent sample and results are presented in Table 4.1.

Table 4.1: Summary table of independent sample t-test showing gender difference in risky driving behaviour among vehicle drivers

DV	Gender	N	Mean	SD	df	t-value	Sig
Risky driving	Male	106	19.94	6.03	118	-5.52	<.001
	Female	14	9.50	7.80			

The results indicated that male participants significantly reported higher risky driving behaviour than their female counterparts $t(116)=-5.52, p<.001$. Table 4.1 also shows that male participants scored a mean of 19.94 on risky driving behaviour while the female scored a mean of 9.50 with a mean difference of 10.44. This implies that gender there is a significant difference in the risky driving behaviour among the drivers sampled. Thus, the hypothesis that stated that there would be a significant difference in the risky driving behaviour based on drivers' gender is accepted

Table 4.2: χ^2 Test of Association on Risky Driving Behaviour by Gender

				Total
		Low	High	
Gender	Male	45 38.1%	61 51.7%	106 89.8%
	Female	10 8.5%	2 1.7%	12 10.2%
Total		55 46.6%	63 53.4%	118 100.0%

$(\chi^2= 7.24, df= 1, p<.05)$

Analysis of the relationship between gender and risky driving behaviour displayed in the Table 4.2 which reveals that a greater proportion (51.7%) of the respondents who are males reported higher risky driving behaviour compared to female respondents. This indicates that there was significant association between age and risky driving behaviour

$(\chi^2= 7.24, df= 1, p<.05)$

Hypothesis two stated that the male driver will be more prone to accidents than female drivers. This hypothesis was analyzed using the t-test for independent samples and the results of the analyses are presented in Table 4.3.

Table 4.3: Summary table of independent sample t-test showing difference gender in accident proneness among vehicle drivers

DV	Gender	N	Mean	Std	Df	t-value	Sig
Accident proneness	Male	106	17.76	8.74	118	-4.03	<.001
	Female	14	27.58	7.90			

Table 4.3 shows that female participants significantly reported higher accident proneness than the male counterpart [$t(116)=-4.03$, $p<.001$]. The table shows that male participants scored 17.76 on accident proneness, while the female scored 27.56 with a mean difference of 9.82. This implies that there is a significant in accident proneness among the drivers sampled. Based on this finding, hypothesis two that stated that there would be significant differences in the male and female drivers' level of accident proneness is thus accepted

Table 4.4: χ^2 Test of association on Accident Proneness by Gender

		Accident Proneness		Total
		Low	High	
Gender	Male	81 68.6%	25 21.2%	106 89.8%
	Female	4 3.4%	8 6.8%	12 10.2%
Total		85	33	118
			28.0%	100.0%

($\chi^2 = 9.93$, $df = 1$, $p < .05$)

Analysis of the relationship between gender and accident proneness displayed in the Table 4.4 reveal that greater proportion (68.6%) of the respondents who were male reported low accident proneness compare to female. This indicates that there was significant association between gender and accident proneness ($\chi^2 = 9.93$, $df = 1$, $p < .05$).

Hypothesis three stated that educational qualification will significantly influence the level of risky driving behavior among injured drivers. This hypothesis was tested using the t-test for independent samples and the summary of the result is presented in Table 4.5

Table 4.5: Summary table of independent sample t-test showing educational status differences in risky driving behaviour among vehicle drivers

DV	Educational status	N	Mean	S.D	Df	t-value	Sig
Risky driving behaviour	Low education	75	20.16	6.77	118	2.62	<.05
	High education	45	16.80	6.82			

Table 4.5, shows that participants with high educational status significantly reported higher risky driving behaviour than participants with low educational status [$t(118)=2.617, p<.05$]. The Table also shows that participants with low educational status scored 20.16 on accident proneness, while those with high educational status scored 16.80 with a mean difference of 3.36. This result demonstrates that there is an educational qualification difference in risky driving behaviour. Based on this, hypothesis 3 stated that educational qualification will significantly influence the level of risky driving behavior among injured drivers was also confirmed.

Table 4.6: χ^2 Test of Association on Risky Driving Behaviour by Educational Status

		<u>Risky driving behavior</u>		<u>Total</u>
		<u>Low</u>	<u>High</u>	
Education	Primary	14	11	25
		11.9%	9.3%	21.2%
	SSCE	16	32	48
		13.6%	27.1%	40.7%
	NCE/OND	12	9	21
		10.2%	7.6%	17.8%
	HND/B.Sc	13	11	24
		11.0%	9.3%	20.3%
Total		55	63	118
		46.6%	53.4%	100.0%

($\chi^2= 5.77, df= 1, p>.05$)

Analysis of the relationship between educational status and risky driving behavior displayed in Table 4.6 reveal that greater proportion (27.1%) of the respondents who acquired SSCE certificate reported high risky driving behaviour compared to respondents with other qualifications. This indicates that there was no significant association between educational qualification and risky driving behaviour ($\chi^2= 5.77, df= 1, p>.05$)

Hypothesis four stated that Individuals with low level education will significantly have higher accident proneness than drivers with high level of education among injured drivers. This hypothesis was tested using the t-test for independent samples and the results of the analysis presented in Table 4.7

Table 4.7: Summary table of independent sample t-test showing educational status differences in accident proneness among vehicle drivers

DV	Educational status	N	Mean	Std	df	t-value	Sig
Accident proneness	Low education	75	17.38	8.46	118	-2.05	<.05
	High education	45	21.00	9.81			

Table 4.7 shows that participants with high educational status significantly reported proneness higher accident than participants with low educational status $t(118) = -2.05, p < .05$. The Table also shows that participants with low educational status score a mean of 17.38 on accident proneness, while those with high educational status scored a mean of 21.00 with a mean difference of 3.82. This suggests that respondents with higher educational qualification exhibited more risky driving behaviour among the drivers sampled.

Hypothesis five stated that younger driver will significantly influence the level of risky driving behaviour among injured drivers. This hypothesis was tested using the t-test for independence and the result presented in Table 4.8

Table 4.8: t-test summary table showing age differences in risky driving behaviour

	Age	N	\bar{X}	SD	DF	T	Sig
Risky driving	Young	38	18.18	6.35			
behavior	Old	80	19.21	7.24	116	-.75	>.05

The result reveals that respondents who are younger (M=18.18, S.D= 6.34) are not significantly different on risky driving behaviour compare to older respondents (M=19.21, S.D =7.24). The result indicates that there was no significant difference in risky driving behaviour reported by older and younger respondents (t (116) = -.75, p>.05). This demonstrates that there are no significant in the risky driving behaviour of the drivers sampled.

Table 4.9: χ^2 Test of Association on Risky Driving Behaviour by Age

	Age	Driving behavior		Total
		Low	High	
	20-25 years	14	10	24
		11.9%	8.5%	20.3%
	26-30 years	29	27	56
		24.6%	22.9%	47.5%
	31 years and above	12	26	38
		10.2%	22.0%	32.2%
Total		55	63	118
		46.6%	53.4%	100.0%

($\chi^2 = 5.38$, df= 2, p>.05)

Analysis of the relationship between age and risky driving behaviour displayed in the table 4.9 reveal that greater proportion 24.6% of the respondents who fall between the age group 26-30 years reported low risky driving behaviour compare to other age groups. This indicates that there was no significant association between age and risky driving behaviour ($\chi^2 = 5.38$, df= 2, p>.05)

Analysis of the relationship between age and risky driving behaviour displayed in the table 4.9 reveal that greater proportion 24.6% of the respondents who fall between the age group 26-30 years reported low risky driving behaviour compare to other age groups. This indicates that there was no significant association between age and risky driving behaviour ($X^2= 5.38$, $df= 2$, $p>.05$)

Hypothesis six stated that younger drivers will significantly more accident prone among injured drivers. This hypothesis was tested using the t-test for independence and the result presented in Table 4.10

Table 4.10: t-test summary table showing the influence of age on accident proneness

	Age	N	\bar{X}	SD	DF	t	Sig
Accident proneness	Young	38	16.24	5.273			
	Old	80	19.96	10.289	116	-2.10	<.01

The result from the Table 4.10, also reveals that younger respondents ($M=16.24$, $S.D= 5.27$) significantly reported lower scores on accident proneness than older respondents with high accident proneness ($M=19.98$, $S.D =10.29$) Older respondents significantly reported more accident proneness than younger respondents $t(116) = -2.10$, $p<.01$). This implies that gender significantly influence accident proneness among the drivers sampled.

Table 4.11: Test of Association on Accident Proneness by Age

		Accident proneness		Total
		Low	High	
Age	20-25 years	24	0	24
		20.3%	0.0%	20.3%
	26-30 years	34	22	56
		28.8%	18.6%	47.5%
	31 years and above	27	11	38
		22.9%	9.3%	32.2%
Total		85	33	118
		72.0%	28.0%	100.0%

($X^2 = 12.89$, $df = 2$, $p < .05$)

Analysis of the relationship between age and accident proneness displayed in the table 4.11 reveal that greater proportion 28.8% of the respondents who fall between the age group 26-30 years reported low accident proneness compare to other age group. This indicates that there was significant association between age and accident proneness ($X^2 = 12.89$, $df = 2$, $p < .05$)

Hypothesis seven States that personality factors and alcohol use will independently and jointly predict risky driving behaviour. This hypothesis was analysed using multiple regression analysis and the summary is presented in Table 4.12

Table 4.12: Multiple Regression Table Showing Predictors of Risky Driving Behaviour among Drivers

Predictor variables	B	T	P	R	R ²	F	P
Neuroticism	.29	3.19	<.05				
Extraversion	-.18	-1.01	>.05				
Conscientiousness	.18	1.39	>.05				
Agreeableness	.25	1.33	>.05				
Openness to experience	-.52	-4.11	<.05				
Alcohol use	.40	4.849	<.05	.57	.29	8.80	<.05

From Table 4.12, the result of the multiple regression shows that all the predictor variables jointly predict risky driving behaviour of injured drivers ($F(6,111) = 8.80$; $p < .05$ with $R = .57$ and R^2 (adjusted) = 0.29. This indicates that all the predictor variables jointly account for 29% of the variation in driving behavior of injured drivers. In terms of independent contribution of neuroticism, ($\beta = .29$, $t = 3.19$; $p < .05$); openness to experience ($\beta = -.52$, $t = -4.11$, $P < .05$) and alcohol use ($\beta = .40$, $t = 4.85$, $p < .05$) independently predict driving behaviour of injured drive. However, the contributions of extraversion ($\beta = -.18$, $t = -1.01$; $p > .05$), conscientiousness ($\beta = .18$, $t = 1.39$; $p > .05$) and agreeableness ($\beta = .25$, $t = 1.33$; $p > .05$) were not significant. Based on this result, the hypothesis 7 stated above is confirmed partially.

Hypothesis eight states that personality factors and alcohol use will independently and jointly predict accident proneness. This hypothesis was analyzed using multiple regression analysis and the summary is presented in table 4.13:

Table 4.13: Multiple Regression Table Showing Predictors of Accident Proneness among Drivers

Predictor variables	β	T	P	R	R^2	F	P
Neuroticism	.04	.39	>.05				
Extraversion	-.59	-2.83	<.05				
Conscientiousness	-.06	-.38	>.05				
Agreeableness	.59	2.75	<.05				
Openness to experience	.22	1.52	>.05				
Alcohol use	-.08	-.83	>.05	.33	.060	2.24	<.05

From Table 4.13, the result of the multiple regression indicates that all the predictor variables jointly predict accident proneness of injured divers ($F(6,111) = 2.24$; $p < .05$) with $R = 0.33$ and R^2 (adjusted) = 0.060. This shows that all the predictor variables could

jointly account for 6% variance observed in the reported accident proneness among injured drivers: Concerning independent contribution, extraversion and agreeableness independently predict accident proneness of injured drivers ($\beta = -0.59$; $t = -2.83$; $p < .05$ and $\beta = 0.59$; $t = 2.75$; $p < .05$) respectively. However, neuroticism, ($\beta = .04$, $t = .39$; $p > .05$); conscientiousness ($\beta = -.06$, $t = -.38$; $p > .05$) openness to experience ($\beta = .22$, $t = 1.52$, $p > .05$) and alcohol use ($\beta = .40$, $t = 4.85$, $p < 0.5$) were found not to independently predict accident proneness of injured drivers. Judging by this result, hypothesis eight is confirmed and supported partially.

Hypothesis 9 stated that all psychological and social variables will significantly predict risky driving behaviour better than personality and alcohol use variables among drivers. The hypotheses were tested using hierarchical regression analysis the results and are presented in Table 4.14.

Table 4.14: Summary of hierarchical regression analysis showing the influence of neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, alcohol use gender, age and education level on risky driving behaviour.

PREDICTORS	MODEL I			MODEL II			MODEL III		
	B	T	P	B	T	P	B	T	P
Neuroticism	.20	2.08	<.01	.29	3.19	<.01	.29	3.63	<.01
Extraversion	-.37	-1.93	>.05	-.18	-1.01	>.05	-.29	-1.83	>.05
Conscientiousness	.13	.92	>.05	.18	1.39	>.05	.14	1.32	>.05
Agreeableness	.44	2.20	<.01	.25	1.33	>.05	.25	1.59	>.05
Openness to experience	-.43	-3.14	>.05	-.52	-4.11	<.01	-.38	-3.43	<.01
Alcohol use				.40	4.85	<.01	.39	5.42	<.01
Gender							-.42	-6.09	<.01
Age							-.05	-.67	
Education							-.10	-1.38	
<i>R</i>		.42			.57		.70		
<i>R</i> ²		.18			.32		.49		
ΔR^2		.142			.286		.461		
<i>Df</i>		5,112			6,111		7,110		
<i>F</i>		4.88			8.80		15.31		

The result of the hierarchical regression analysis tested if personality traits incrementally contributed to risky driving behaviour compared to alcohol and demographic variables. First the result in Table 4.16 revealed that neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, alcohol use, gender, age and education level significantly predicted risky driving behaviour among drivers ($R^2 = 0.42$, $F = 4.88$, $df = 5,112$, $p < .001$). Neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, alcohol use, gender, age and

education level were found to predict 18% of the variance observed in the risky driving behaviour among drivers. The result further reveals that neuroticism ($\beta = .20$, $t = 2.08$, $p < .001$) and agreeableness ($\beta = .44$, $t = 2.20$, $p < .001$) were significant independent predictors of risky driving behavior among drivers.

The introduction of the “alcohol use” into the model revealed that personality factor explained an incremental 14% of the variance observed in risky driving behavior ($R^2 = 0.57$, $\Delta R^2 = 0.14$, $F = 8.80$, $df = 6, 112$, $p < .001$). Results revealed that the addition of alcohol use revealed that neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, gender, age and education level contributed significantly to the change observed in the prediction of risky driving behavior ($R^2 = 0.32$, $\Delta R^2 = 0.27$, $F = 8.80$, $df = 4, 112$, $p < .001$). Neuroticism ($\beta = .29$, $t = 3.19$, $p < .001$), openness to experience ($\beta = -.52$, $t = -4.11$, $p < .001$) and alcohol use ($\beta = .40$, $t = 4.85$, $p < .001$).

The result also revealed that the addition of the present demographic variables contributed about 17% to the variance observed in the level of risky driving behavior among drivers. The result revealed that the addition of present demographic factors revealed that neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, alcohol use, gender, age and education level contributed significantly to the change observed in the prediction of risky driving behavior among drivers ($R^2 = 0.49$, $\Delta R^2 = 0.66$, $F = 15.31$, $df = 7, 110$, $p < .001$). Neuroticism ($\beta = .29$, $t = 3.69$, $p < .001$), openness to experience ($\beta = -.38$, $t = -3.43$, $p < .001$), alcohol use ($\beta = .39$, $t = 5.42$, $p < .001$), gender ($\beta = -.42$, $t = -6.09$, $p < .001$) remained significant independent predictors of risky driving behavior, while the influence of Age, educational level were negligible in the model.

Hypothesis ten stated that psychological and social variables will significantly

predict accident proneness better than personality and alcohol use variables among drivers. The hypothesis was tested using hierarchical regression the result presented in table 4.15.

Table 4.15: Summary of hierarchical regression analysis showing the influence of neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, alcohol use, gender, age and educational level on accident proneness.

PREDICTORS	MODEL I			MODEL II			MODEL III		
	β	T	P	β	t	p	B	T	P

Age							.10	1.46	>.05
R		.320			.329		.566		
R²		.103			.108		.321		
ΔR^2		.063			.060		.271		
Df		5,112			6,111		7,110		
F		2.56			2.41		6.43		

The result of the hierarchical regression analysis showing the incremental contribution of personality factors to risky driving behaviour compared to the contribution of alcohol and demographic variables. First the result in Table 4.15 revealed

that neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, alcohol use, gender, age and education level significantly predicted accident proneness among drivers ($R^2 = 0.10$, $F = 2.56$, $df = 5,112$, $p < .001$). Neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, alcohol use, gender, age and education level were found to significantly predict 10.3% of variance observed in the accident proneness among drivers. The result further reveals that extraversion ($\beta = -.55$, $t = -2.72$, $p < .001$) and agreeableness ($\beta = .55$, $t = 2.64$, $p < .001$) were significant independent predictors of accident proneness among drivers.

The introduction of the alcohol use revealed that personality factor explained an incremental 5% of the variance in accident proneness ($R^2 = 0.11$, $F = 2.41$, $df = 6,112$, $p < .001$). Results revealed that the addition of alcohol use revealed that neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, alcohol use, gender, age and education level contributed significantly to the change observed in the prediction of accident proneness ($R^2 = 0.11$, $\Delta R^2 = 0.06$, $F = 2.41$, $df = 6,112$, $p < .001$). Extraversion ($\beta = -.59$, $t = -2.83$, $p < .001$), and agreeableness ($\beta = .59$, $t = 2.75$, $p < .001$) were significant independent predictors of accident proneness among drivers.

The result also revealed that the addition of the present demographic variables contributed about 22% to the variance in the level of accident proneness among drivers. The result revealed that the addition of present demographic factors revealed that neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, alcohol use, gender, age and education level contributed significantly to the change observed in the prediction of accident proneness among drivers ($R^2 = 0.32$, $\Delta R^2 = 0.27$, $F = 6.43$, $df = 7,110$, $p < .001$). Extraversion ($\beta = -.52$, $t = -2.83$, $p < .001$), agreeableness ($\beta =$

.52, $t = 2.75$, $p < .001$) educational level ($\beta = .39$, $t = 4.42$, $p < .001$) and gender ($\beta = .35$, $t = 4.33$, $p < .001$) remained significant independent predictors of risky driving behaviour, while the influence of Age is negligible in the model.

UNIVERSITY OF IBADAN LIBRARY

CHAPTER FIVE

DISCUSSION, CONCLUSION AND RECOMMENDATION

5.1 DISCUSSION

The major purpose of this study is to contribute to the prevention of untimely death caused by road traffic accident. This contributes to the literature on personality factors and alcohol use, risky driving behaviour and accident proneness. Besides, it is the aim of this study to examine the role played by these variables. The study reveals a wide range of causes of road traffic accident, over speeding, drunkenness, lack of experience and risky driving behaviour.

In chapter four, ten hypotheses were proposed on the relationship between the personality factors and risky driving behaviour, personality factors and accident proneness, alcohol use and risky driving behaviour, alcohol use and accident proneness. Likewise, socio-demographic factors were hypothesized to play role in risky driving behaviour and accident proneness. Among the ten hypotheses tested, seven hypotheses out of the ten were fully supported.

Hypothesis one which stated that male driver will be more prone to risky driving behaviour than female drivers among injured drivers was confirmed. Male participants significantly reported higher risky driving behavior than the female counterpart. This finding is similar to that of Özkan and Lajunen (2006) who found that being male is significantly associated with more Highway Code violations. Moreover, in another study by Deffenbacher et al., (2003) they found that men scored higher on aggressive driving behaviour than their female counterparts.

Bogg and Roberts (2004) in meta-analysis review of 21 studies that revealed that males behave in a riskier manner than females while driving though this behavior tends to decrease with age revealed that conscientiousness traits were negatively related to all risky health-related behaviors. Males behave in a riskier manner than females and these risky types of behaviour tend to decrease with age. Risky driving styles were associated with being male and young (Elander et al., 1993). Drivers especially males, often use vehicles to show-off, to attract attention or impress members of the opposite sex, to obtain excitement and to display competitive courage among young women (Arnett et al., 1997; Jonah, 1997; Kohler, 1996; Iram & Taubman, 1994).

The study found significant differences in the male and female drivers' level of accident proneness was confirmed. Female participants significantly reported higher accident proneness than the male counterpart. This finding is in line with Chen and Zhou (2014) who demonstrated that guardian's gender and gender of child were among the salient factors influencing accident proneness in rural children. Women to be too critical and in some cases unconsciously negligent of safety rules and procedure especially

The study result implicated education level in risky driving behaviour. The study found the significant influence of educational qualification on risky driving behaviour among injured drivers. Participants with higher educational status significantly reported more risky driving behaviour than participants with low educational status. This finding is also in consonance with the study of Rowe, Maugham, Gregory and Eley (2013) who found that attitudes became riskier more accidents proneness obtained the more training and driving experience was acquired between these two time points. Drivers who received certificate in driving were more likely to endorse risky driving behaviours than either non-

drivers or learner drivers. Riskier attitudes were associated with having held a full license for longer, having clocked up more driving miles, and having committed more speeding violations.

This study also demonstrated that individuals with low level of educational qualification will significantly reported higher accident proneness than drivers with high level of education among injured drivers was supported. Participants with high educational status significantly reported higher accident proneness than participants with low educational status. This suggests that respondents with higher educational qualification exhibited more risky driving behaviour among the drivers sampled.

This finding is similar to Begg, Langley, Stephenson (2003) they investigated factors that predicted persistent driving after drinking, persistent unsafe driving after drinking and persistent cannabis use and driving among young adults. They found that mental health measures (substance use, cannabis dependence, alcohol dependence, depression); anti-social behaviour (juvenile arrest, aggressive behavior, court convictions); early driving behaviour and experiences (car and motorcycle licences, traffic crashes) and gender predicted risky driving behaviour. The results showed that males who persisted in driving after drinking were more likely than the other males to have some school academic qualifications and to be employed at age 26.

This study did not confirm the influence the age significantly influence the level of risky driving behaviour among injured drivers. The result demonstrated that age did not play a major role in risky driving behaviour among the drivers sampled. This finding is in contrast to the studies that have established that being young have significant effect on risky driving among young drivers (McKnight & McKnight, 2000, 2003). The study

also contrasted studies which found that accident incidence decline with a bus driver's age (Dorn & afWahlberg, 2008).

The result of the study found that the age of drivers significantly influence their level of accident proneness. Respondents above 35 years of age reported more accident proneness than younger respondents. The finding is similar to a study which found that accident incidence decline with a bus driver's age (Dorn & afWahlberg, 2008). The negative association between age and accidents is in accord with some studies (Lourens et al., 1999; Zuckerman, 2008). The findings supports that of Schlag (1994) who found that Older people were slower to merge on motorway access slip roads, chose a tighter turning radius when turning into a minor road and in general tried harder to drive in the right-hand lane. They ignored priority rules and red lights significantly more often. Older people frequently ignored other drivers who had priority, and they crossed a level crossing without barriers without reducing their speed.

A major finding in this study is that personality factors and alcohol use independently and jointly predict risky driving behaviour among injured drivers. Openness to experience, conscientiousness, extraversion, agreeableness, neuroticism personality traits and alcohol use jointly predicted the level of accident proneness among the injured drivers. Neuroticism, openness to experience personality traits and alcohol use were independent predictors of accident proneness. Respondents who were high on neuroticism personality trait and alcohol use but low on extraversion and openness to experience traits were more prone to being in accidents situations compared to those low on neuroticism personality trait and alcohol use but high on extraversion and openness to experience traits. Neuroticism emerged as the significant predictor of group assignment

when we controlled for antisocial attitudes, although there was no significant difference in the scores between both groups. Many authors have also found a positive relation between neuroticism and aggressive driving, as a particular risky driving behaviour. With regard to criminality, Ozer and Benet-Martínez (2006) reported a positive relation between neuroticism and antisocial behavior in general. Ozer and Benet-Martínez (2006) reported a negative relation between conscientiousness and antisocial behavior in general and criminal behaviour. These findings are similar to findings from past studies. Neuroticism is a fundamental personality trait characterized by anxiety, moodiness, worry, envy, and jealousy. They respond more poorly to stressors, they are more likely to interpret ordinary situations as threatening and minor frustrations as hopelessly difficult. They are often self-conscious and shy, and they may have trouble controlling urges and delaying gratification.

The literature on driving has revealed that motivations like competitiveness, sense of power and control, or just pursuing sensual pleasure may impinge on the way one drives and may influence a person's decision to drive recklessly. The study also supports the findings of Aworeni et al., (2011) that there is relationship between human characteristics, vehicular characteristics, roadway characteristics, environmental characteristics. The findings also demonstrated support for a study that found the significance relationship between extraversion or introversion traits and accident proneness.

This finding is similar to Liao et al. (2001) who found that fire-fighters who were introverts were less likely to call for assistance and as fire-fighting requires a high degree of teamwork; it might be that the less integrated and sociable members of the team

exposed themselves to greater personal risks. Extroversion is associated with being impulsive and this has been found to be a feature in people who have car accidents and accidents at work (Furnham and Heaven, 1999). These apparently contradictory findings show how personality characteristics can interact with the situation someone is in and the type of task they are asked to carry out so as to produce an unsafe environment. Another dimension included in “driving errors of commission” deals with the fact of driving after drinking alcohol which is also a crucial risky driving dimension (Curry, Ludman, Grothaus, Donovan & Kim, 2003). Other equally important variables were included in the first factor: driving during bad weather conditions, driving while using mobile phone and overtaking in dangerous situations. Secondly, the factor “distraction” is associated to the distractive behavior. A study conducted by Deffenbacher et al. (2003) leads to the conclusion that lapses of concentration are associated with risky driving behaviour.

In line with previous studies (Blanchard, Barton & Malta, 2000; Dahlen & White, 2006; Lajunen & Parker, 2001; Schwebel et al., 2006) driver’s personality is a good predictor of dangerous driving behavior. Conscientiousness was also found to be a good predictor of group assignment, and negatively related to DUI. Some authors have also reported the importance of conscientiousness in distinguishing between DUI offender and the normal population (Hubicka et al., 2010), but no relation was found between this personality trait and other unsafe driving behaviours (Dahlen and White, 2006).

The findings on alcohol use which demonstrated that drivers crashed whilst under the influence of alcohol in the United States (Williams et al., 2011). In the same vein studies which demonstrated that substance-impairment may reduce wearing of seatbelt and increase the number of passengers (Calligeros, 2009).

The study also identified that personality factors and alcohol were independent and joint predictors of accident proneness, The findings in the hypothesis suggest that extrovert are prone to frequent accident, similar result were found in the work of Iversen, and Rundmo(2002) this corroborates the results from previous studies that show that personality characteristics is significantly relating to driving. Fergusson, Swain-Campbell, and Horwood (2003) who examined the prevalence of risky driving behaviour among young people, the characteristics of those who engage in risky driving behavior and the association between risky driving behaviors and accident risk. More than 90% of drivers engaged in some form of risky driving behaviour.

Those who are likely to engage in frequent risky driving behaviors were: males who exhibited alcohol or cannabis abuse use. There was a strong association between the extent of risky driving behaviour and traffic accident risk. This result is similar to that of Iversen,-Hilde; Rundmo,-Torbjorn(2000) who found that drivers involved in risk taking-behavior experienced near-accidents and crashes leading to both injuries and material damage more often than other drivers. A Similar result was found by Huebner, Porter-Marshall (2006). In the same vein, Begg and Langley (2004) found that personality trait of low constraint (i.e. low scores for control, harm avoidance, and traditionalism), aggressive behavior, and cannabis dependence predicted risky driving behaviour. Schell and colleagues also found correlation between driving under influence of alcohol (DUI) and Impulsivity and Hostility. Ulleberg and Rundmo (2003) also found that the effect of personality on risky driving in young drivers was mediated by traffic safety attitudes.

The findings also supports Scott-Parker, Watson, King and Hyde (2014) who demonstrated that substance-impaired driving was associated with avoiding Police,

speeding, risky driving intentions, and self-reported crashes and offences. Forty-three percent of respondents who drove after taking drugs also reported alcohol-impaired driving. Risky behaviour of concern include drink driving, speeding, novice driving errors such as misjudging the speed of oncoming vehicles, violations of graduated driver licensing passenger restrictions, driving tired, driving faster if in a bad mood, and active punishment avoidance. Given the interrelationships between the risky driving behaviours, a deeper understanding of influential factors is required to inform targeted and general countermeasure implementation and evaluation during this critical driving period.

The results on the study combination of all psychological and social variables whether they significantly predict risky driving behaviour better than personality and alcohol use variables among drivers was supported. The addition of demographic factors and personality traits to experience, alcohol use and gender, age and education level contributed significantly to the change observed in the prediction of risky driving behaviour among drivers. Neuroticism, openness to experience, alcohol use, and gender were the important independent predictors of risky driving behaviour, while the influence of age, educational level were negligible in the model. This finding is synonymous with studies that have been documented that personality traits and demographic characteristics predicting risky behaviours.

The findings also support Iversen and Rundmo (2002) they examined relationships between personality, risky driving and involvement in accidents and who found the prediction of recklessness, sensation seeking, and locus of control and driver anger on risky driving, accident involvement. The findings also support the study of YILMAZ and ÇELİK (2006) whose study focused on driver factors in traffic accidents and was carried

out in order to show risky drivers' attitudes tendency, especially. The study found that inclusion of sex, education level; age and driving experience have an incremental prediction of risky drivers reported while the remaining two were partially supported based on the results analyzed.

Lastly the study demonstrated the combined effect of psychological and social variables to the prediction of accident proneness among drivers. The result revealed that psycho-social model predicted accident proneness better than personality and alcohol use among injured drivers independently. The result revealed that the addition of present demographic factors revealed that neuroticism, extraversion, conscientiousness, agreeableness, openness to experience, alcohol use, gender, age and education level contributed significantly to the change observed in the prediction of accident proneness among drivers. Extraversion, agreeableness, educational level and gender remained significant independent predictors of risky driving behaviour, while the influence of Age is negligible in the model. This also similar to Chen and Zhou (2014) who found that that gender, academic record, left-behind status family type, family economic status, guardian's gender, guardian's marital status, guardian's occupation, and family educational mode were influencing factors for accident proneness in rural children. Low grade and very low grade in academic record, poverty in family economic status and indulgence or indifference and fickleness in guardian's educational mode were risk factors for accident proneness in rural children, while female gender was a protective of the young children.

5.2 CONCLUSION

- A) This study has examined personality factors (agreeableness, conscientiousness, extraversion, openness and neuroticism) and alcohol use as predictors of risky driving behavior (speed, reckless driving, overtaking) and accident proneness. The researcher developed a scale which measure risky driving behaviour. This contributes a tool for screening drivers for risky driving behavior. Drivers found to score high could be counseled about safe driving behavior, deconditioning them so that they can adopt a safer and better driving behaviour
- B) The result of the study demonstrated that personality factors (openness, conscientiousness, extraversion, agreeableness and neuroticism) jointly predicted risky driving behaviour with personality traits contributing 29% of the variations. Independently, neuroticism, openness and alcohol use significantly predicted risky driving behaviour. Moreover, openness, conscientiousness, extraversion, agreeableness, neuroticism and alcohol-use jointly accounted for 6% variation in accident proneness. However only extraversion and agreeableness significantly independently predicted accident proneness. It was concluded that alcohol and personality factors influenced the prevalence of accidents proneness on Nigeria roads.
- C) The result has demonstrated that demographic factors influenced the level of risky driving behaviour and accident proneness with gender and education playing dramatic role. The result demonstrated that female participants were more prone to accident than their male counterpart. In addition, those who had higher education qualification were more frequently involved in accident situations compared to

those with lower education. Male drivers exhibited higher risky driving behaviours than female drivers.

- D) Those with lower educational qualification exhibited higher risky driving behaviour than those with higher education. This suggests on the road assessment and psychological assessment should be conducted for both commercial and non-commercial drivers to identify the risky drivers before issuance of driver's license and periodic re-evaluation with psycho-education be adopted. This findings suggest that present practice of clinical health psychology there is need to include psychologists especially the clinical health psychologist to work as members of multidisciplinary teams in the public health sectors to provide psycho-education and cognitive behavior therapy for those who engage in risky driving behaviour.

5.3 RECOMMENDATIONS FOR FUTURE RESEARCH

A single study cannot examine all the relevant issues to the accident prevention. With the shortcomings already identified therefore, prospective researchers are advised to involve in other areas like Climate, Road infrastructure, safety officers, and Personality factors of offending drivers. Interventions to prevent alcohol impaired driving may need to influence the factors that mediate the link between driving behaviour and accident proneness.

Based on the above discussion, it would be recommend that reference to the special on-road dynamics would be included in driver training for both drivers and private car drivers. An emphasis that drivers must cope with other road users and attempt to better understand and anticipate their on-road decisions may be appropriate. Identification of

anxious driving behaviors and recognition of factors contributing to their development may be useful in guiding intervention for those seeking assistance with travel-related anxiety. Relationships observed in the current study identify personality as a common vulnerability factor for risky driving among individuals with a history of traffic collisions. There is however a critical need to establish a formal Program on Anger Management, with a focus on mitigating those factors already highlighted as provoking driver anger, leading in most cases to aggressive driving. It is therefore implicit that an anger management program is as well an aggressive driving management program in practice.

Anger management programs are usually based on the assumption that angry and aggressive drivers are unable to identify and manage their anger; this is understandable because many drivers may have the comforting feeling that it is the other drivers who make all the errors and violations in traffic situations involving road crashes. To be sure, as it is the case with other anger problems, aggressive drivers do not seek help because of their limited self-awareness and a tendency to see the other driver as the problem. Self-referral to anger management programs is thus rare. Almost always, participants enter anger management programs at court mandates or at the request of lawyers, or family members.

The results of the assessments are then discussed with the client and an individual intervention plan is developed. On the whole, the object of the therapy is to moderate attitudes and perceptual styles that increase the risk of anger and aggressive driving, to desensitize and improve regulation of mood and state of arousal, and to develop healthier coping strategies and safer driving behavior.

Impulsive behavior can also be moderated by a spirit of forgiveness and consideration of future consequences as proposed by Moore and Dahlen (2008). A driver who tends to consider future behavioural consequences may drive less aggressively because the consequences of aggressive driving would be more pronounced, thereby increasing the chances of driver awareness in that direction. The implication is that Driver Education programs which include supplementary defensive driver curricula with strategies to control anger and promote forgiveness may be useful for safer road usage even in the Nigerian environment.

Without doubt, enforcement efforts in Nigeria have improved considerably in many facets. The Federal Road Safety Corps has also made commendable improvements in the standardization of driver training and education in Nigeria. These efforts should now be accompanied by public information campaigns aimed at influencing driver behavior with regard to the traffic states unraveled in the study described. Beyond these efforts, however, there is an urgent need to widen the scope of education for transport use in Nigeria. Such a program is currently being considered, in the context of formal education, but it should include virtually all road user groups.

Ignorance about elementary and basic facts regarding traffic safety is widespread even among educated Nigerian transport users and it is more so among illiterate road users. There is, therefore, the need to embark on an effective program of training and retaining of transport users. For such a training program to arrest the increase in road crash as well as 'near crash' or Conflict situations, it must be directed towards the enhancement of the road user behaviour and the improvement of his skills to make the correct decisions in traffic situations. In fact, the role of transport user education is so vital

that road safety training should be included in the elementary and secondary schools curricula. The objectives of education for transport use must be fully spelled out. It should be clear that the aim is to enable every Nigerian citizen to acquire accurate perceptions of risks together with appropriate norms for taking them.

The introduction of transport user education in elementary and post-primary schools curricula will ensure that, in the long term, every Nigerian citizen would have acquired the appropriate transport user skills. Immediate road safety education is needed for every social group, including those who are beyond schooling age. This may be provided through an outreach program of the FRSC Training School/Academy in collaboration with existing Zonal Commands. The training media could be through the organization of regular teaching clinics, instruction programs in the television networks, and instruction manuals in English as well as in local languages.

It means that the target group to educate consists of every social group, including children, teenagers, pedestrians, all. It is no longer enough to assume that it would be well with every user group, once drivers and motorists mastered the traffic codes and acquired an attitude of safe driving and consideration for other road users. Children and pedestrians are indeed the most vulnerable among the groups of transport users.

5.4 SUGGESTIONS FOR FURTHER STUDY

Based on the enumerated limitations of the study, any investigator who wants to replicate this study should endeavour to increase the sample size and involve more states. The effects of cultural differences and dangerous driving should also be studied so that

there would be comparison among the different parts of the country on the variables of issues.

5.5 LIMITATIONS OF THE STUDY

Several features of the present study limit the conclusions that could be drawn and suggest directions for future research. The limitation of the current study needs to be addressed.

The study population, consisting of respondents that were victims of trauma associated with severe pain, grief was limited to Teaching Hospital in Osun State, hence data gathering was limited to one health facility in the state, and respondents were predominantly people from that state. One significant impediment in the study's design was that respondents had limited time available to complete the questionnaire because the ward routine prevents them to give full attention to extra engagement. Another impediment was that the state ministry of health has no standard provision for traumatized patients.

Lastly, there was no proper police accident data to compare with that of Federal Road Safety Corps (FRSC).

APPENDIX

**UNIVERSITY OF IBADAN
DEPARTMENT OF PSYCHOLOGY
IBADAN**

Dear Respondent,

This questionnaire before you is just a tool to tap information purely for academic purposes and any information provided will be treated with utmost confidentiality. Your cooperation is therefore required in making this work a success.

SECTION A: Demographic Information

Please describe the following characteristics about yourself as much as possible.

1. Age:
2. Gender: Male.....Female.....
3. Religion: Christianity.....Islam.....Traditional.....None.....
4. Years/ Length of training.....
5. Marital Status: Single.....Married.....
6. Educational qualifications: Primary.....SSCE.....
NCE/OND.....HND/B.Sc.....
- 6b. Occupation.....

SECTION B: Accident Proneness Questionnaire:- This section is to measure occurrence of accident that you might have involved in. Please tick the answer appropriate to you.

S/N	Accident Proneness	Nearly	Almost Near	Often	Sometimes often	Some what all the time often	Nearly all the time
7	Many drivers don't have enough skills of driving safely on the road						
8	Many drivers don't have enough knowledge about highway code						
9	It happens regularly that drivers make mistakes						
10	It happens regularly that driver don't follow the safety regulations						
11	Many drivers believe too much on luck						
12	Regularly other road users do things that cause accident						
13	Generally speaking driving on our roads is not safe						
14	Did you witness a serious car accident on the roads in the last 3 years						
15	Did you witness one or more accidents on the roads during the last three years?						
16	If yes, were you involved in the accident yourself						

SECTION C: This section is to measure driving behaviour. Please answer each of the following question as honest as possible.

S/N	Driving Behaviour	Never	Rarely	Sometimes	Often	Always
17	I drive when I am angry					
18	I lose my temper when driving					
19	I consider the actions of other drivers to be inappropriate or stupid					
20	When I get stuck in a traffic Jam I get irritated					
21	I feel that passive drivers should learn how to drive or stay home					
22	I flash my headlights when I am annoyed by another driver					
23	I make rude gestures (For example giving “the finger”, yelling curse words) toward drivers who annoy me					
24	I verbally insult drivers who annoy me					
25	I deliberately use my car/truck to block drivers who tailgate me					
26	I would tailgate a driver who annoys me					
27	I will illegally pass a car/truck that is going too slowly					
28	I will drive if I am only mildly intoxicated or buzzed					
29	I will cross double yellow lines to see if I can pass a slow moving car/buzzed					
30	I will drive when I am drunk					
31	I consider myself to be a risk taker					

SECTION D: This section is to measure substance use (ALCOHOL USE)

Instruction: Read the following item below and tick as they apply to you

- 0 - Not Applicable
- 1 - A long time after a month
- 2 - Occasionally
- 3 - Everyday

S/No	Item	0	1	2	3	4
32	How often do you have a drink containing alcohol					
33	How much drink containing alcohol do you have on a typical day when you are drinking?					
34	How often do you have five or more drink on any occasion?					
35	How often during the last years have you found that you were not able to stop drinking ones you started?					
36	How often during the last year you have found that you failed to do what was normally expected from you because of drinking?					
37	How often during the last year have you found that you needed a first drinking in the morning to get yourself going after a heavy drinking session?					
38	How often during the last year have you found that you had a feeling or guilt or remorse after drinking?					
39	How often during the last year have you found that you are unable to remember what happened the night before because you had been drinking?					
40	Have you or someone else got injured as a result of your drinking?					
41	Has a relative or friend or a doctor or health worker been concerned about your drinking or suggested you cut down?					

SECTION E

Please read each statement carefully, and then tick the one that correspond to your reply

Strongly, Agree (SA), Agree (A), Undecided (U), Disagree (D), Strongly Disagree (SD)

S/No	Items	SA	A	U	D	SD
42	I have frequent mood swings					
43	I am not easily bothered by things					
44	I am skilled in handling social issues					
45	I make plans and stick to them					
46	Sometimes I dislike myself					
47	I do respect other people so much					
48	I easily insult people so much					
49	I seldom feel blue (moody)					
50	I don't like to draw attention					
51	I do carryout my plans as scheduled					
52	I am interested in abstract ideas					
53	I make friend easily					
54	I tend to vote for liberal political candidate					
55	I know how to captivate people					
56	I believe that others have good intentions					
57	I do just enough work to get by					
58	I do find it difficult to get down to work					
59	I always carry conversation to a higher level					
60	I avoid philosophical discussion					
61	I accept people as they are					
62	I do not enjoy going to art museums/club					
63	I pay attention to details					
64	I kept in the background					
65	I feel comfortable with myself					
66	Often times, I waste my time					
67	I do get back at others					
68	I get chores done right away					
69	I don't talk a lot					
70	I sometimes shirk my duties					
71	I often feel blue (moody)					
72	I easily cut other to pieces					
73	I have a good word for everyone					
74	I don't see things through					
75	I feel comfortable around people					
76	I make people feel at ease

PROTOCOL NUMBER LTH/EC/2012/11/0123
PROJECT TITLE: *Predictors of Accident Proneness among Injured Drivers in LAUTECH Teaching Hospital, Osogbo*
INVESTIGATOR(S): Mr. Akinniyi, Rotimi Jacob
DEPARTMENT / INSTITUTION: Department of Psychiatry, University of Ibadan, Oyo State, Nigeria
SUBMISSION OF PROTOCOL: APRIL, 2012
FINAL CONSIDERATION: OCTOBER, 2012
DECISION OF THE COMMITTEE: **APPROVED**
CHAIRMAN: Prof. Oluwadiya K. S (FMCS)
SIGNATURE & DATE:

NOTE: THE COMMITTEE IS EXEMPTED FROM LIABILITY OF THE PROPOSAL AND THIS CERTIFICATE WILL BE REVOKED IF PROTOCOLS STATED IN THE PROPOSAL IS DEVIATED FROM.

DECLARATION BY INVESTIGATOR (S)

PROTOCOL NUMBER (Please quote in all enquiries): LTH/EC/2012/11/0123

To be completed in four and three copies returned to the secretary, Ethics and Research Committee, Ladoke Akintola University of Technology Teaching Hospital, Osogbo, Osun State, Nigeria.

I/We fully understand the conditions under which I am/we are authorized to conduct the above - mentioned research and I/We will ensure compliance with these conditions. Should any departure be contemplated from the research procedure as approved, I/We undertake to resubmit the protocol to the Ethics and Research Committee.
