Background: The COVID-19 pandemic has disrupted routine hospital services globally. This study estimated the total number of adult elective operations that would be cancelled worldwide during the 12 weeks of peak disruption due to COVID-19.

Methods: A global expert response study was conducted to elicit projections for the proportion of elective surgery that would be cancelled or postponed during the 12 weeks of peak disruption. A Bayesian β -regression model was used to estimate 12-week cancellation rates for 190 countries. Elective surgical case-mix data, stratified by specialty and indication (surgery for cancer *versus* benign disease), were determined. This case mix was applied to country-level surgical volumes. The 12-week cancellation rates were then applied to these figures to calculate the total number of cancelled operations.

Results: The best estimate was that 28 404 603 operations would be cancelled or postponed during the peak 12 weeks of disruption due to COVID-19 (2 367 050 operations per week). Most would be operations for benign disease (90.2 per cent, 25 638 922 of 28 404 603). The overall 12-week cancellation rate would be 72.3 per cent. Globally, 81.7 per cent of operations for benign conditions (25 638 922 of 31 378 062), 37.7 per cent of cancer operations (2 324 070 of 6 162 311) and 25.4 per cent of elective caesarean sections (441 611 of 1 735 483) would be cancelled or postponed. If countries increased their normal surgical volume by 20 per cent after the pandemic, it would take a median of 45 weeks to clear the backlog of operations resulting from COVID-19 disruption.

Conclusion: A very large number of operations will be cancelled or postponed owing to disruption caused by COVID-19. Governments should mitigate against this major burden on patients by developing recovery plans and implementing strategies to restore surgical activity safely.

Introduction

The COVID-19 pandemic has led to major disruption of routine hospital services globally¹. During the pandemic hospitals have reduced elective surgery in the interests of patient safety and supporting the wider response^{2–4}. Reducing elective activities protects patients from in-hospital viral transmission and associated postoperative pulmonary complications. This preserves personal protective equipment supplies to be prioritized for the care of patients with COVID-19, and releases ward and critical care beds for surges in such patients. It also enables recovery areas in theatre suites to be repurposed as overflow ICUs. Surgeons and theatres teams may be redeployed to support other critical areas of the hospital.

Cancelling elective surgery on this scale will have a substantial impact on patients and cumulative, potentially devastating, consequences for health systems worldwide⁵. Delaying time-sensitive elective operations, such as cancer or transplant surgery, may lead to deteriorating health, worsening quality of life, and unnecessary deaths^{6–8}. When hospitals resume elective activities, patients are likely to be prioritized by clinical urgency⁹, resulting in lengthening delays for patients with benign but potentially disabling conditions where there may be less of a perceived time impact. This will lead to a deterioration in population health, productivity and a substantial societal cost.

Worldwide cancellations in elective surgery are currently unquantified^{10,11}. Few countries have access to real-time

HDI, Human Development Index.

data, and even those that do may experience delays in this information being released owing to pressures on health systems. Estimating country-level estimates will provide the best possible baseline data to inform planning for post-pandemic surgical recovery. This study aimed to estimate the total number of elective operations that would be cancelled or postponed worldwide during the 12 weeks of peak disruption of hospital services owing to COVID-19.

Methods

The study methodology is summarized in *Fig. 1*. First, an expert response study was undertaken to elicit surgeons' projections of the proportion of elective surgery that would be cancelled during the peak 12 weeks of disruption owing to COVID-19. These data were fed into a Bayesian β -regression model to estimate 12-week cancellation rates for elective surgery for 190 countries. Second, elective surgical case mix was determined for each Human Development Index (HDI) quintile using data from the Surgical Outcomes Studies and the expert response study. This case mix was applied to existing figures for overall country-level surgical volume to calculate expected specialty-specific surgical volumes for 190 countries. Finally, these surgical volume figures and the 12-week cancellation rate estimates

were used to calculate total numbers of cancelled operations by specialty and country.

All 193 United Nations member countries were included in this study except Liechtenstein, North Korea and Somalia, as no surgical volume data were available for these three countries¹². At present, the only region to have recovered from a large-scale SARS-CoV-2 outbreak is Hubei Province in China. Wuhan, the capital of Hubei, was in lockdown for 76 days (23 January 2020 to 8 April 2020). Therefore, the current best estimate for the duration of disruption to health systems caused by COVID-19 is around 12 weeks. This is consistent with advice that hospitals should plan to suspend non-urgent elective surgery for at least 12 weeks⁴.

The secondary outcomes were total number of cancelled operations stratified by World Bank region (Europe and Central Asia, East Asia and Pacific, Latin America and the Caribbean, North America, Middle East and North Africa, South Asia, Sub-Saharan Africa), World Bank country income group (high, upper-middle, lower-middle, low), and surgical specialty. Specialty-specific cancellation totals were calculated for surgical specialties accounting for 5 per cent or more of the global surgical case mix (*Table S1*, supporting information). This included colorectal, head and neck, gynaecological, orthopaedic, obstetric, plastics,

Table 1 Best estimates of cancelled operations over a 12-week period of peak disruption, by specialty group

	Normal volume*	Estimated cancellations	12-week cancellation rate (%)
Cancer surgery			
Colorectal	1 353 952	486 563	35.9

Total	39 275 857	28 404 603	72.3

*Surgical volume at full capacity (no cancellations).

upper gastrointestinal (including hepatobiliary surgery) and urological surgery. Colorectal, head and neck, gynaecological, plastics, upper gastrointestinal and urological surgery were further stratified into operations performed for cancer *versus* benign pathology. Orthopaedic surgery was not stratified in this way as cancer accounts for a very small proportion of orthopaedic operations. Specialties that individually account for under 5 per cent of surgical case mix were pooled into an 'other surgery' category, including breast surgery, cardiac surgery, neurosurgery, thoracic surgery and vascular surgery. Therefore, a total of 15 specialty groups were included in this study (Table 1).

Twelve-week elective surgery cancellation rates

Senior surgeons were invited to participate in an expert response study to elicit their projections for the proportion of elective surgery that would be cancelled during the peak 12 weeks of disruption owing to COVID-19. Surgeons were contacted through the global CovidSurg network and asked to enter their estimates into an online database. The questionnaire was open from 20 to 30 March 2020.

Experts were asked to provide estimates for each of the 15 specialty groups included in this study. For each specialty group, experts provided their best estimate (the most likely 12-week cancellation rate), as well as a lower

bound estimate (the lowest possible cancellation rate) and an upper bound estimate (the highest possible cancellation rate). If the SARS-CoV-2 outbreak had resolved at the experts' hospital, they were asked to report actual rates of cancelled surgery due to the outbreak. If the outbreak was ongoing, experts were asked to project likely cancellation rates going forward. If the experts' hospital had not yet experienced a SARS-CoV-2 outbreak, they were asked to estimate what would happen in the event of an outbreak.

After the expert response study questionnaire had closed, responses were matched by hospital and, where there was more than one expert participating per hospital, median values for each data point were calculated, so that there was one consolidated response per hospital. Overall median values for the best estimate and upper/lower bounds were then calculated for each participating country for cancer surgery, surgery for benign disease and obstetric (elective caesarean section) operations.

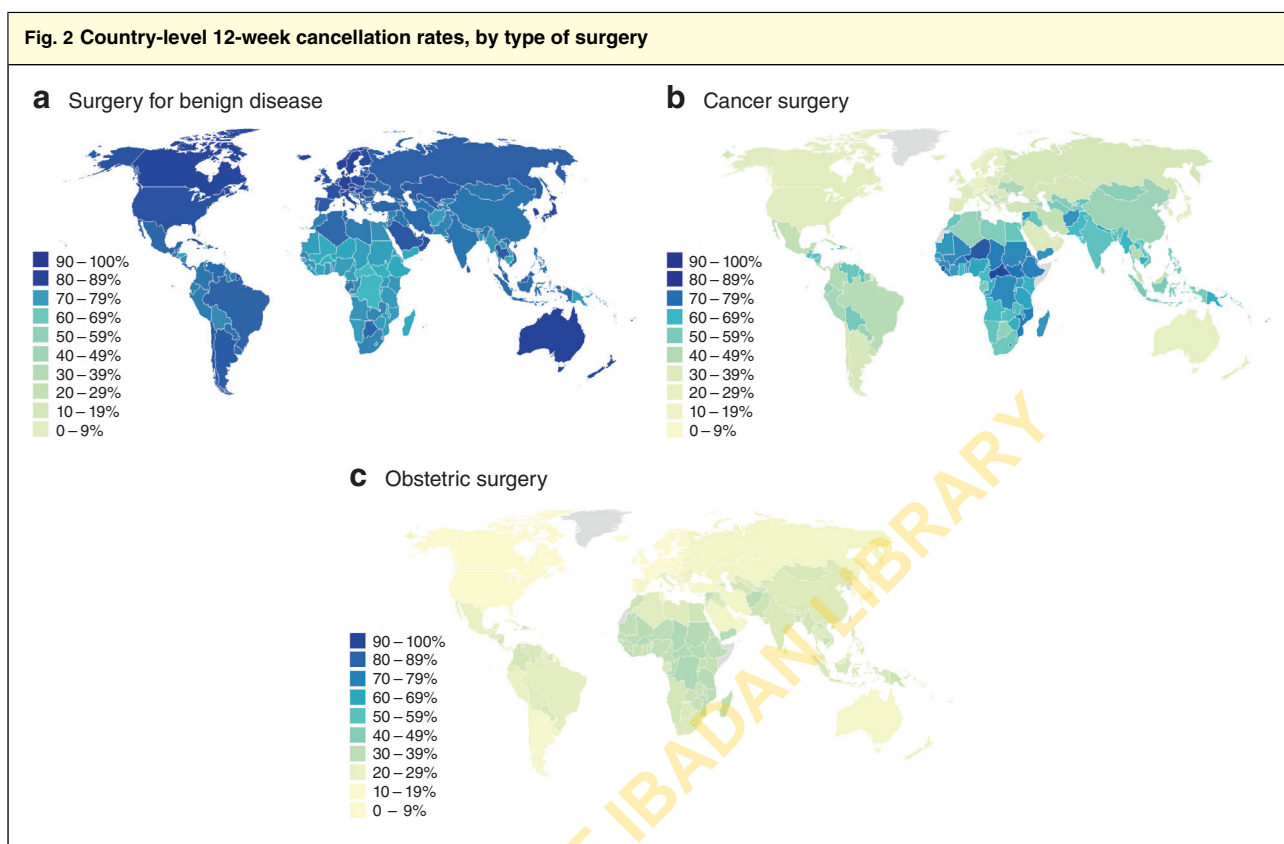

A Bayesian β -regression model was developed with 2018 HDI as a predictor, in order to establish 12-week cancellation rate estimates for all 190 countries included in the study (Table S2, supporting information). HDI is a composite index of life expectancy, education and per-capita income indicators, and its relationship with surgical outcomes has been validated previously^{13,14}.

Non-informative priors were used with sensitivity analyses done on alternative priors and different chain initiation points or chain lengths. A restricted cubic spline transformation was applied to the continuous representation of the HDI rank (rank 1 being the most developed country and rank 190 the least developed) to account for potential non-linearity. This was substituted into the final β -regression model and posterior predictions were made for each HDI rank. The model was fitted for the best estimates and lower/upper bounds for cancer surgery, surgery for benign disease and obstetric (caesarean section) operations.

Surgical case mix

The best available global data on surgical case mix are from the African Surgical Outcomes Study, European Surgical Outcomes Study and International Surgical Outcomes Study¹⁵⁻¹⁷. These were prospective cohort studies that captured all adults undergoing surgery in participating facilities, providing case-mix data for a total of 102 539 patients across 64 countries. No comparable global case-mix data exist for paediatric surgery, so this study was limited to adults.

Raw data from the three Surgical Outcomes Studies were pooled to estimate case mix by HDI quintile (Table S2, supporting information). First, the case mix was determined

a Surgery for benign disease, **b** cancer surgery and **c** obstetric surgery.

according to urgency: elective *versus* emergency. Next, within elective surgery the case mix was stratified by specialty. To determine cancer *versus* benign surgical case mix, the expert response study participants were asked to estimate the proportions of colorectal, head and neck, gynaecological, plastics, upper gastrointestinal and urological operations performed in their hospitals for cancer. Hospital-level results were then pooled by HDI quintile to calculate median proportions of cancer surgery for each specialty.

Surgical volume

A previous report¹² identified total country surgical volume for 72 countries (presented as point estimates) and modelled estimates for a further 120 countries (presented as confidence intervals). As only overall total (paediatric surgery) country volumes were available, population age-structure data from the World Bank were used to estimate total adult surgical volume for each country. Adults were defined as people age 15 years and above, consistent with age categories used for population data by the World Bank.

Country-level surgical volumes for each of the 15 specialty groups included in this study were calculated based on the country-specific adult surgical volume and case mix for the appropriate HDI quintile. For the best estimate of total cancellations, the point estimate (if provided) or the midpoint of the confidence interval for country-level surgical volume was used to calculate specialty-specific country-level surgical volume.

Totals for cancelled surgery

Country-level surgical volume data and modelled 12-week cancellation rates were used to calculate specialty group-specific totals for adult elective operations cancelled during the peak 12 weeks of disruption. The best estimate for the number of cancelled operations was based on the modelled best estimates for 12-week cancellation rates.

Surgical recovery

Values in parentheses are weekly total of cancelled operations for each country.

to COVID-19 was estimated. It was assumed that cancelled obstetric (caesarean section) operations would not need to be rescheduled after the pandemic. Therefore, the time taken to clear country-level backlogs of operations for benign disease and cancer was based on country-level baseline volumes of surgery for these conditions. The number of whole or part weeks needed to clear these backlogs was calculated based on 10, 20 and 30 per cent increases in baseline surgical volume.

Sensitivity analyses

An estimate for the minimum number of operations likely to be cancelled was based on the lowest likely baseline surgical volume (the lower bounds for total surgical volume estimates where provided) and the modelled lower bounds for 12-week cancellation rates. An estimate for the maximum number of operations likely to be cancelled was based on the highest likely baseline surgical volume (the upper bounds for total surgical volume estimates where provided) and modelled upper bounds for 12-week cancellation rates.

Analyses were done using R version 3.6.3 and rstan (the R interface to the statistical inference language Stan) and the packages brms and finalfit (R Foundation for Statistical Computing, Vienna, Austria).

Results

Twelve-week cancellation rates

From a total of 538 submissions to the expert response study (*Fig. S1*, supporting information), data were available for 359 hospitals in 71 countries (*Table S3*, supporting information). Proportions of surgery projected to be cancelled were consistently estimated to be higher for benign conditions than for obstetrics (elective caesarean sections). Proportions of cancer surgery projected to be cancelled were lower in the most developed countries compared with the least developed ones (*Fig. S2*, supporting information).

Based on the Bayesian β -regression model, best estimates for country-level 12-week cancellation rates for cancer surgery ranged from 23.4 to 77.1 per cent, whereas they

Values are best estimate (range). There are some small inconsistencies between totals due to differences in how figures have been rounded.

ranged from 71.2 to 87.4 per cent for surgery for benign conditions, and from 17.4 to 37.8 per cent for obstetrics (*Fig. 2; Table S4*, supporting information).

Surgical volume

The best estimate for cancellations was based on a global annual adult elective surgical volume of 170 195 382 operations (*Fig. S3*, supporting information). Details of surgical case mix are provided in *Tables S5–S8* and *Figs S4–S7* (supporting information).

Total cancellations

The best estimate was that 28 404 603 operations would be cancelled or postponed globally during the peak 12 weeks of the COVID-19 pandemic. Worldwide 2 367 050 operations would be cancelled per week, with 11 countries cancelling more than 50 000 operations per week (*Table 2*).

Most of the cancelled or postponed operations were estimated to be for benign disease (90.2 per cent, 25 638 922 of 28 404 603), followed by cancer (8.2 per cent, 2 324 070 of 28 404 603) and obstetrics (1.6 per cent, 441 611 of 28 404 603) (*Table 1*). The best estimate was that the global 12-week cancellation rates would be 72.3 per cent (28 404 603 of 39 275 857) overall, 81.7 per cent (25 638 922 of 31 378 062) for benign disease surgery, 37.7 per cent (2 324 070 of 6 162 311) for cancer surgery and 25.4 per cent (441 611 of 1 735 483) for obstetrics (*Table 3*).

Overall, 12-week cancellation rates by World Bank region would range from 68.3 to 73.0 per cent. The most cancellations were projected to take place in Europe and Central Asia (8 430 348 procedures) and the least in Sub-Saharan Africa (520 459) (*Fig. 3* and *Table 4*), reflecting the low baseline surgical volume there. Country-level totals stratified by specialty are presented in *Table S9* (supporting information).

Surgical recovery

Based on a 20 per cent increase in baseline surgical volume, it was estimated that it would take countries a median of 45 (range 43–48) weeks to clear the backlog of operations resulting from 12 weeks of disruption due to COVID-19 (Table S10, supporting information). If baseline surgical volume were increased by 10 per cent, it would take countries a median of 90 (86–95) weeks to clear the backlog, whereas with a 30 per cent increase in baseline surgical volume this would take a median of 30 (29–32) weeks.

Sensitivity analyses

The minimum estimate was that 19 849 153 operations would be cancelled worldwide during the 12 weeks of peak disruption due to COVID-19 (1 654 096 per week), representing a 61.1 per cent 12-week cancellation rate (19 849 153 of 32 488 250). The maximum estimate was that 43 945 672 operations would be cancelled during the peak 12 weeks (3 662 139 per week), representing a 12-week cancellation rate of 86.2 per cent (43 945 672 of 50 960 625).

Discussion

This study has demonstrated the major burden of cancelled elective surgery due to the COVID-19 pandemic. Although a similar proportion of surgery will be cancelled across different country income settings and geographical regions, the greatest number of cancellations will be in upper-middle-income countries. Cancer surgery will be prioritized in most settings, with most cancellations relating to surgery for benign conditions, most frequently orthopaedics.

The risks of exposing patients to perioperative SARS-CoV-2 infection by performing surgery during outbreaks are high, but must be weighed against the risks of protracted treatment delays. Given that many health systems already lack sufficient capacity to meet the need for surgery¹⁸, the impact of cancellations will be cumulative, adding to existing waiting lists. Governments will need to fund substantial increases in baseline surgical volume to clear backlogs, but this is likely to be costly. For example, based on an average cost of £4000 per operation, it would cost over £2 billion to clear the UK's backlog.

There is a risk that delayed treatment of benign conditions as a result of pandemic-related cancellations will lead to deterioration in individual patients' conditions, increasing disability and reducing their ability to work. This will lead to substantial societal costs, particularly

in low-middle income countries (LMICs) where catastrophic expenditure relating to surgical disease can lead to impoverishment^{19,20}.

This study has several limitations. Although estimates were based on the best available global surgical data, several assumptions were required. As the COVID-19 pandemic is ongoing, it was necessary for the expert response study participants to project forward their estimates for 12-week cancellation rates. Participants in countries where the pandemic was in its earliest stages, such as in Sub-Saharan Africa, may have had to base their estimates on experience in previous emergencies, rather than the specific circumstances of COVID-19. The uncertainty around these estimates was captured by recording both lower and upper bounds, as well as best estimates for 12-week cancellation rates. Surgical case mix was based principally on snapshot cohort studies that collected data across 64 countries^{15–17}. Given the barriers to participation in research, particularly in LMICs²¹, it is unknown how representative these data are of the global case mix. Most countries do not publish surgical volume data, so this study relied on previous estimates of country-level surgical volume.

The eventual geographical extent and intensity of the pandemic is currently unknown, but it is likely that most countries will be affected^{22–24}. The country-level figures can be used to produce estimates of cancellations per week, allowing policymakers to adjust estimates according to the predicted duration of local outbreaks. Prediction of the impact of COVID-19 on elective surgery in local communities can inform local planning and resource prioritization.

Postpandemic surgical recovery planning should anticipate the possibility of repeat waves of SARS-CoV-2 infection²⁵, leading to additional periods of cancellation of elective surgery. Therefore, strategies to safely maintain surgical volume during and immediately after SARS-CoV-2 outbreaks should be explored. For example, time-sensitive surgery, such as cancer resection, can be performed in designated non-COVID-19 units that do not treat patients with COVID-19. Although the optimal organization of such surgical units is unknown, it is likely that they should carefully select low-risk patients who are unlikely to require intensive care and can be operated safely in satellite units. Both patients and staff will require rigorous screening to reduce the risks of cross-infection. Surgical recovery plans should also consider that an immediate return to high-volume surgery may not be possible. For example, adaptations to operating theatres, such as installation of negative pressure flow systems, may need to be expedited to reduce the delay to resumption of normal activity.

Future research should be prioritized to identify strategies to mitigate the risk of operating in COVID-19

environments, so that cancellations are minimized. For example, although ongoing trials are testing treatments for COVID-19^{26–28}, large randomized trials are also needed to test therapies to prevent postoperative COVID-19 pulmonary complications.
